178. **Induced Pneumothorax in Treatment of Pulmonary Tuberculosis.**—Persch discusses this subject from various points of view and reports four cases to show the great benefits liable to be derived in certain cases. The effect surpassed all anticipations in his first case, the patient a woman of 27 with various complications of pulmonary tuberculosis of several years' standing. The second case shows the simplicity and ease of the technic and the benefit even of a brief course of treatment. In the third the patient was moribund but the fatal termination was postponed for over three weeks by the immobilization of the lung. The fourth case is particularly instructive: this patient was a young woman with rapidly progressing tuberculosis, apparently restricted mostly to the left lung, the exacerbation following childbirth. The pneumothorax was induced about five months after the childbirth and clinical recovery followed, notwithstanding an exceptionally unfavorable environment.

179. **Hemolytic Reaction in Cancer.**—Kelling reports further experiences with 200 cases which confirm his recent assertions in regard to a hemolytic reaction in the diagnosis of a not yet palpable cancer. The test seems to show that in the serum with cancer there is something which gives a specific reaction with chicken blood-corpuscles. His research has shown that there is not only a hemolytic ferment for fowl blood-corpuscles but also a hemolytic immune body, an amboceptoid and a substance which deviates complement. He describes the technic for this test and for a further hemolytic reaction in which hemolysis is inhibited.

181. **Extradural Anesthesia.**—Lieven reports his experiences with an anesthetic injected according to Cathelin's epidural technic in six obstetric and fifty operative gynecologic cases. In the latter he used a very complicated technic, throwing the patients into a twilight sleep before making the extradural injection. In the obstetric cases the extradural technic has the disadvantage that anesthesia does not come on for about twenty minutes and that it puts an end to the abdominal straining during delivery. The introduction of the anesthetic is not always easy, and the anesthesia induced is not of long enough duration for protracted operations.

182. **Return of Menstruation After Curetting.**—Jaeger states that in twenty-five cases in which the curetting was done for endometritis and in twenty-five for the results of abortion, menstruation did not seem to be affected. He accepts this as evidence that menstruation does not depend on the uterine mucosa but on the functioning of the ovaries.

183. **Toxic Action of Blood in the Abdominal Cavity.**—Bröse reports three cases which show the possibility of an extremely toxic action from blood escaping into the abdominal cavity. Two of the women died. The chief symptoms were the paralysis of the entire intestines coming on the second or third day after rupture of a tubal pregnancy or operation for pyosalpinx or fibromyomas accompanied by much hemorrhage. The paralysis of the intestines was accompanied by high temperature and accelerated pulse, somnolency and agitation. According to his experience fluid blood seems to have a more toxic action than the coagulated.

STREPTOTHRICOSIS (ACTINOMYCOSIS) OF THE LUNGS*

NORMAN BRIDGE, M.D.
LOS ANGELES

In 1908 I reported[1] seven cases of what I believed to be pulmonary actinomycosis (streptothricosis) discovered in one year. Since then several additional cases have been encountered. They have all been infested by a streptothrix which I have supposed to be the *Streptothrix actinomyces.* Some of these patients have also had tuberculosis, death resulting in each case; some have had simple streptothricosis; several of these have recovered.

Of the former series three patients had also pulmonary tuberculosis and all were free from infection in other parts of the body. In one case (No. 2, N., of the mixed disease) the patient, who had a marked lesion of the left lung, had died April, 1908, after a year's struggle and eight months after coming under observation.

In another mixed case (No. 3, G.) the patient survived till March, 1909. In this case there was little involvement of the lungs, the apices only being invaded, especially the right. The larynx was profoundly involved, with much swelling, swallowing being difficult and painful, and aphonia being absolute for many months before death.

Case 1.—The patient, A., was reported probably cured, had remained so to a recent date, the recovery apparently being permanent. This was the most marked and characteristic case of the series, almost the whole of the left lung being more or less diseased, the patient having expectorated large quantities of bloody malodorous muco-pus for many weeks, often a pint or more in twenty-four hours, and recovering with a mass of consolidated tissue in the left upper third, with reduced vesicular murmur and bronchial breathing over the whole lung.

Case 4.—The patient absconded and has not been rediscovered.

Case 5.—The patient had mixed disease, went east and his fate is unknown.

Case 6.—M., the patient, seemed to pass into recovery with a rather marked consolidation in the bottom of the left lung posteriorly, and a lesser one in the right apex. Marked fibrosis occurred, especially in the left side, which greatly reduced the motion of the chest-walls—in fact, nearly abolished it; the breathing was mostly abdominal, and even moderate exertion caused extreme dyspnea. Yet the man looked well and, barring the short-windedness, felt so. A few actinomycetes were found in his expectoration after the first report, but none for several months before his death—indeed, for many weeks there had been no expectoration of pus. The man went to Colorado in 1909, was seized with some complication and died in two or three days.

Case 7.—W., the patient, had a marked lesion in the lower left chest posteriorly, with free expectoration of thick bloody sputum (his case having been early taken for one of some extraordinary pneumonia—as indeed it was), completely recovered, with evidence of moderate thickening of tissue (so-called consolidation) in the region involved. His health is apparently perfect.

Case 8.—Of the second series of cases, the first was a mixed one, the patient (B.) being a bachelor, aged 25, a lawyer. He came under observation late in July, 1908, and had then been sick for fifteen months. At first his expectoration was bloody; for a year it had not been over a half ounce in twenty-four hours, and blood-free. The lesion was a diffused and moderate one throughout the left lung. It gradually grew worse, with more and more signs of consolidation; dulness, reduced motion, bronchial breathing, râles, reduced vesicular murmur, especially at the bottom of the lower lobe, and finally a cavity. He failed and died in April, 1910. Both tubercle bacilli and actinomycetes were found in the expectoration and were distinct and typical.

Case 9.—R., the patient, is a vigorous-looking bachelor, a street-car conductor of 28 years. He was first seen in December, 1908. He felt poorly and coughed for several months. Expectoration had been moderate in amount and occasionally bloody. A few actinomycetes were found but no tubercle bacilli. There was almost an entire absence of physical signs, barely slight bronchial breathing in the right apex. The germs have increased in the sputa. There has been little or no fever, and he keeps his weight and general condition; the daily expectoration is about three ounces, and it is occasionally bloody, and fetid. Early in 1910 his nose apex swelled, got red and finally broke down in ulceration of the skin in numerous small points. The streptothrix was found in the discharges from the ulcers. The condition recovered under tincture of iodin locally and iodin internally. Later a similar ulceration occurred on one of his legs above the ankle and healed.

Case 10.—H., the patient, of Wyoming, came under observation March 22, 1909. He is a sheep raiser, 52 years of age, married. The previous autumn he had what was pronounced left pneumonia and was in bed four or five days. He was expectorating 8 ounces of pinkish muco-pus every twenty-four hours; had no fever, but was very short-winded; he had lost 15 pounds in weight. The expectoration teemed with actinomycetes. He had manifestly extensive effusion in the left pleural cavity which was aspirated March 25 of the amount of 20 ounces of pinkish sero-pus containing what appeared to be débris of actinomycetes. March 31, the left side remaining still flat, a drainage-tube was inserted which promptly discharged 30 ounces of fluid. There was no lesion of the right lung, so the expectoration manifestly came from the upper part of the left lung and may in part have come through a perforation from the pleural cavity, since after the drainage the expectoration was reduced markedly. The patient soon returned home and his doctor reported for a time a moderate improvement. He returned to Los Angeles in the winter of 1909-10. Actinomycetes in fragments were still found in the discharges. An operation for removal of sections of ribs was done after his return home in the spring of 1910.

Dr. Robert Kellg Library
[illegible] Medical College

CASE 11.—C., the patient, was in the practice of my associate, Dr. George L. Cole, with a record as follows: He had come under observation December 3, 1908. He was a lumberman, 62 years of age, had been well since 1870 until eight or ten months before; then a cough began and there was pain in the left chest. He was put to bed by his previous physician during January and February, 1908, having been aspirated four times up to April of that year. About one quart of fluid was procured each time.

His pulse was weak and cough bad (Dec. 3, 1908), although expectoration was trifling. Dr. Cole found complete dulness over the left chest, the heart being pushed to the right; the apex-beat was distinctly to the right of the sternum. The patient was aspirated of between 3 and 4 quarts of bloody fluid; but the little expectoration that was procured contained actinomycetes. Jan. 29, 1909, the left side was still profoundly dull throughout. There was tactile fremitus down to the fifth rib, also voice sounds. The heart apex was under the sternum. This was substantially the condition April 23, 1909. There was no real vesicular murmur even at the apex. There was no fever; pulse and respiration were rapid. The weight had decreased 24 pounds. Yet, the patient was about, attending to business daily and looked like a man only slightly under normal vigor. He grew gradually worse and died Nov. 4, 1909. The left lung was found compressed into the size of a large human fist. The right lung had become extensively invaded, at the apex, by what the microscope showed to be carcinoma.

CASE 12.—C., the patient, is a single woman aged 40, who has had tuberculosis and has been coughing more or less for a number of years. She has also had a great deal of nervous debility. Her previous physicians found tubercle bacilli on several occasions.

On my examination made in 1908 her right lung had slightly reduced motion, marked reduction in vesicular murmur, trifling dulness and sharp bronchial breathing at the top, reduced fremitus over the middle and lower portions, trifling bronchial breathing at the top of the left lung. The patient was not expectorating much and it was impossible to procure a good sputum specimen. Her temperature was 1 degree above normal. Hers was regarded as an arrested case of tuberculosis.

After an absence of a year she returned for another examination. She had recently been having fever—to 102 F.—with wheezing, cough and poor appetite. There was now marked consolidation of the lower part of the right lung posteriorly and about the same condition as before in the upper portion. No tubercle bacilli were present in the sputum, but numerous actinomycetes.

The patient had not lost much in weight and her general functions were fairly normal. She had been in very fair health the previous year, except for some irregularities in menstruation. She soon ceased to have fever. The thickening at the base of the right lung disappeared and general improvement was noticeable. Occasionally she had a recurrence of slight fever, with numerous râles throughout the right lung. It was evident that the infection was in the right apex. The actinomycetes mostly disappeared after a few months, and her general health was greatly improved, when she suddenly developed a rather marked case of exophthalmic goiter. This improved after a few months. She is now in fair health, but recently a few actinomycetes were found.

CASE 13.—C., a man of 40, widower, an office man from Philadelphia, came under observation May, 1909. His general health was good; his appearance was that of a well man; his general functions as to digestion and general vigor were normal. He had no fever and probably had had none. He had been hoarse more or less for six months and had had a cough with a small amount of expectoration of a thin purulent character, with occasional streaks of blood. The hoarseness was worse in the mornings, better evenings. There had been no difficulty or pain in swallowing. He was only slightly short-winded.

His eastern physicians had repeatedly searched his expectoration for tubercle bacilli and had failed to find any, and one of them had searched for the germs supposed to belong to syphilis, with negative results. He had received free doses of potassium iodid from the last-mentioned physician, who regarded the case as syphilitic (although the patient denied the possibility of it) and reported improvement for a time under the treatment. The patient confirmed this last statement.

Physical examination of the chest (May, 1909) revealed absence of dulness and râles; the slightest possible reduction of vesicular murmur over the upper left chest, and a sort of loud bronchial breathing over both apices, of a character suggesting tracheal narrowing. The larynx was extensively diseased; all the tissues were swollen; the epiglottis was swollen, ulcerous, and cleft rather deeply in its center longitudinally; the vocal cords were swollen and red, and the false cords and arytenoid regions were large and red but apparently not ulcerous. It was impossible to get a good view of the vocal cords and the lining of the trachea. There were two white ulcerous patches on the front of the left half of the soft palate. The sputum contained a few streptococci and many actinomycetes of a typical appearance but no tubercle bacilli.

The patient was advised to have his throat sprayed with an 8 grain water solution of sulphate of copper, and to take ⅓ grain of the copper drug and 6 grains of sajodin, three times a day. He soon disappeared and was not seen again. He died in February, 1910.

CASE 14.—T., a married woman, aged 50, was first seen in February, 1909. She had a laparotomy some months previously for gall-bladder symptoms, followed by some amelioration. She had all the physical signs of a moderate infiltration of what appeared to be tuberculosis of the right apex anteriorly. She had slight fever, moderate expectoration and general debility. No tubercle bacilli were found after repeated examinations, and no actinomycetes until June 10, when a single granule was discovered. Afterward, numerous typical ones were found, some of them in clumps. Later, bloody expectoration in small quantity appeared for a short time with extension of dulness and reduced vesicular murmur in the back of the right apex down to the upper part of the central third of the lung. Fever increased with this extension of the disease. The fever subsided simultaneously with the discharge of larger masses of the peculiar germs. This cycle was repeated several times during the year; extension of the disease and fever, the latter subsiding on the discharge of a large mass of bloody pus with terrible odor. The patient died in 1910. The postmortem findings are reported below. This case occurred in the house of one of the cured patients reported above.

CASE 15.—D., a widow, 65 years of age, had had a moderate cough for a year or more, with a little daily yellow expectoration. In 1908 I found slight physical signs of thickening in the right lung apex. The general health was good for a person of her age. She was a large woman and had lost little weight; she had been substantially without fever. Early in October, 1909, she had had a slight pulmonary hemorrhage and continued to expectorate blood-flecked and odorless sputa for several weeks. No other symptoms occurred. Repeated examinations of her sputa failed to find either tubercle bacilli or actinomycetes, until after this hemorrhage. Then the ray specimens were found in small numbers, but no tubercle bacilli. Early in December, 1909, she was seized with a flooding pulmonary hemorrhage and died in a few minutes. No necropsy was made.

CASE 16.—F., an unmarried man aged 26, a clerk in a chemical and apparatus supply house in Los Angeles for some years, had had cough for several months with a little odorless expectoration, and has lost a few pounds in weight. He has felt a sense of general debility, but has kept at work. There has been less than 1 degree elevation of temperature in the afternoons. Slight dulness, an occasional râle and moderate bronchial breathing have been found at the right apex. Characteristic actinomycetes were found but no tubercle bacilli.

CASE 17.—The patient, Br., in the practice of Dr. Robert Moody of the University of California, at Berkeley, was a single woman, a teacher, 40 years old, with extreme lateral curvature of the spine. Her father had had asthma fifteen years and died of heart disease; one brother died of tuberculosis. The patient had pleurisy in 1903, and the next year, tuberculosis of the right lung. Dr. Moody first saw her in January, 1908. There was a cavity in the right lung; tubercle bacilli and actinomycetes were found in the sputum. Tuberculin was given (1/500 to 1/1000 mg. weekly) till May, 1910, when the tubercle germs disappeared. Streptothrix germs have persisted and the patient was still living a few weeks ago.

The treatment of these cases has been tonic and regulation of functions with iodin in some form and frequently sulphate of copper. The latter was given in doses of 1/3 gr. three times a day when the stomach could bear it, and the iodin in the form of iodid of potassium, or of sodium, and sajodin.

The cases here reported emphasize the fact that pulmonary streptothricosis is not so very uncommon; that most physicians can discover examples if they will only look for them, and that it must be true that a large proportion of the cases of so-called non-tuberculous phthisis are instances of pulmonary streptothricosis of some variety. The number of cases of this sort is considerable and most general practitioners have encountered them and have been puzzled by them.

This whole series proves that it is futile to try to connect the cases with the disease in cattle or in other people. Patient 1 was a farmer, but denied ever having seen a case of lumpy jaw. Patient 3 was a lawyer who took milk from a dairy found to contain some cows afflicted with tuberculosis and fewer cows afflicted with lumpy jaw. The other cases were free of any suggestion as to such an origin of the disease. Case 14 is the only one that appears to have been connected with any other case.

The patients mostly came from widely separated parts of the country and had no connection with each other. Nor was a single case of the lung affection secondary to a lesion elsewhere in the body, and in no instance has the disease appeared secondarily in other organs than the lungs and pleura, save Case 9, in which the skin became involved and recovered.

Dr. Edith Claypole, who has done most of the laboratory work on the specimens, has by means of various devices made a large number of cultures from several cases, and with notable results that are set forth in her notes accompanying this paper. By Gram-stain and otherwise she has been able to demonstrate in the sputum the mycelial threads and rod-segments many days before they appear in masses large enough to give the peculiar radiating appearance so characteristic of the *Streptothrix actinomyces*—indeed, in the early stage she feels able to predict that the larger masses will be found later. This is, I think, a discovery of distinct value. She suggests that any specimen of sputum containing faint blue-staining bacilli in notable numbers, which persistently refuse to grow in ordinary media and are Gram-positive, should be critically searched for the streptothrix with almost a certainty of finding it.

The appearance of the germs, both to the naked eye and magnified, has tallied with the classic description of *Streptothrix actinomyces*, except that there have been no true "clubs," and it has been substantially the same in all the patients. Several authors who have discussed this phase of the subject, notably McFarland, regard the clubbing as merely incidental and unessential in the growth of the germs. This is the correct view, and the clubs are most unusual in the human pulmonary infection,[2] for the reason that being probably a sort of byproduct and depending on the character of the host-tissue, the lungs do not favor their growth. Neither do they grow in any of our culture media. The essential elements are the mycelial threads and their fragmentations, rods and granules, and they tend to gather in masses with certain characteristics that have given the name "actinomyces" to some of them.

The presence in most of the cases of bloody expectoration at some period of the disease, and especially the frequent bad odor, indicate true *Streptothrix actinomyces*. But, of course, some other variety of streptothrix might possibly produce all the phenomena noted in these cases, and they may represent more than one variety. That the germs are an incident and not an etiologic factor in the cases described is quite impossible. The causative relation to the disease is as certain for these germs (whatever their classification) as is that of tubercle bacilli for pulmonary tuberculosis. There may, indeed, be a close biologic relation between the streptothrix and the tubercle germs, but if such is the case it does not appear to be so clinically.

Dr. Claypole has written the following note and discussion on the specimens, and on the pathology of the disease:

In the majority of cases the sputum is characteristic and of two types; (1) glairy, mucilaginous, often quite watery; (2) purulent, more or less bloody, more or less—sometimes intensely—fetid. Both types may be found sparingly or in abundance. The second type may only have a characteristic, homogenous, pinkish color, or be deeply blood-stained; it generally has a distinctly bad odor. This odor may belong in some degree to both kinds of sputum, but especially to the purulent form. Of eight cases, not complicated with tuberculosis, three were in Class 1 and five in Class 2.

The small granules, usually the size of a very small pinhead, can be picked out with a needle and put on a slide for examination. They are quite tough and can be washed free of debris by putting them into a small dish of water and squirting them vigorously up and down a pipette. Careful examination of many specimens before and after this treatment shows them to be absolutely unhurt by it; only the pus and epithelial cells clinging to the outside are removed.

Under a low magnification (Reichert objective 1 and ocular 1) the yellow color is marked; to the naked eye the fungus is greyish white. The edge is always darker, even shading into brown; toward the center it grows lighter. From this light, almost homogeneous center, the characteristic radiations arise. Higher magnification (Reichert objective 7 and ocular 1) shows the center to be a mass of pale, radiating threads, the mycelium, and at the edges a mass of threads and cocci. Both mycelium and cocci may be stained with methyl blue, the former frequently being banded light and dark in segments, sometimes granular throughout.

---

Scheele and Petrusky: Deutsch. med. Wchnschr., 1897, xxiii.
Wagner, C.: Surg., Gynec. and Obst., 1910, x, 148.

Culturally, the actinomycetes do not grow usually on plain agar, glycerin and glucose agar, or potato (they do not seem to be more active on one than on the other of these media); if they are present, there are small whitish masses on the surface, which on removal give the characteristic appearance under the microscope. In bouillon the germs grow better.

In Case 14, T., long bacilli are recorded as found in the sputum at first and later the characteristic granules of streptothrix. In all probability these bacilli, so-called, are fragmented mycelium; ultimately the fungus appeared in masses of tangled mycelia rather than in granules, but always some material of this sort was found. In about eight months a cavity appeared at the apex and the lung involvement became more extensive, especially posteriorly.

When death occurred, the emaciation was extreme. The left lung and pericardium were normal; the right was contracted and anteriorly over the third and fourth rib cartilages, the parietal and visceral pleuræ were densely adherent and the bone involvement marked, explaining the neuralgia and substernal pains complained of. When the adhesions were separated the lower part of the pleural cavity was found to contain 8 ounces of most fetid pus. For a few days before death the patient had coughed up quantities of this fetid fluid, at times almost suffocating in it, showing a bronchial communication with the cavity.

The upper lobe of the lung was mottled black and white, was almost solid in consistence, no porous structure remaining: it contained several small cavities from the size of a pea to that of a walnut. The middle lobe was dark red, spongy, with whitish spots, and anteriorly a white, honey-combed area that was adherent to the sternum for a space of some 3 inches. This was evidently the most recent involvement.

The lower lobe was contracted, reddish and somewhat porous. The diaphragmatic pleural surface was much thickened and resembled a pyogenic membrane. The same mycelial masses were found in this fetid pus as had been observed in the sputum. When the lung was cut into, the same granules and mycelial masses were found in the larger bronchial tubes, together with the debris of pus and epithelial cells. There was no evidence of any lymphatic involvement in any of the bronchial or other glands.

The microscopic examination of the tissues demonstrated the growth of the fungus from the earliest stage to the mycelial masses. Sections were made from the consolidated apex, the middle lobe near the adherent portion, the intercostal tissue, the reddish lung near the base and a piece of the thickened inferior pleural surface of the lower lobe. Some sections were stained with hematoxylin and eosin, and others by the Gram-Weigert method.

As shown in the hematoxylin-eosin mounts, the upper lobe consisted of a large amount of fibrous material, much new granulomatous tissues but no alveoli. The bronchial tubes of varying sizes remained more or less full of sputum, and scattered among the granulomatous tissues were giant cells, not like those accompanying tuberculosis, but small, with only from four to eight nuclei. Never was there any sign of caseation; everything was dense and compact. In the other lobes there was some vesicular structure, but the alveoli were full of desquamated epithelial and pus cells.

Throughout the lung patches of new-formed granulomatous tissue, with its accompanying small giant cells, were of frequent occurrence, showing tissue response to some form of irritation. In places a fine fibrillar structure was plainly seen, often apparently in circular spaces, suggesting blood-vessels. This was of especial interest, as will be seen from the revelations made by the application of the Gram-Weigert method to the same set of sections.

In a recent series of lectures by Foulerton in the London *Lancet* the whole subject of streptothricosis is most ably discussed, and the complex [illegible] demonstrated. The reproduction [illegible] of rod-segments, very similar in appearance and morphologically equivalent to bacilli, as well as by spores, is an especially illuminating phase of the problem and one which gives an entirely new point of view from which to investigate all the tissues in this disease. The Gram stain shows these small particles in the newly infected areas, when other methods fail to do so.

In this case the point of most recent invasion is the area of the middle lobe adherent to the chest wall. This is the point at which the study logically begins. The tissue is more nearly normal than elsewhere, some exudation into the alveoli and some granulomatous cells are present. In one of the largest bronchioles full of pus cells and other elements of sputum, the most beautiful picture of the method of invasion is found. Rod-segments, staining blackish with Gram stain, literally swarm in one place among the pus cells. High columnar epithelial cells surround this mass of sputum. At one point their integrity is broken, and in among the cells are masses of these black rod-segments en route to the deeper tissues. Again, they are found in the intercellular connective tissue and even to the fibrous tissue surrounding the small blood-vessels. This is of especial interest in view of the fact that in older areas of infection these open spaces with walls apparently like those of vessels are found filled with mycelial threads staining the characteristic blue. The good condition, relatively speaking, of all the tissues entirely negatives the idea that this is a process of discharge into the bronchiole, rather than an invasion of it. Of course, it is a condition of self-infection but it shows how the disease extends, and also accounts for the rather slow manner of extension, that of contiguity, not by infection through the blood-stream.

The development of these rod-segments into the typical mycelial masses is the next point for demonstration. The earliest stage of the growth of the mycelium from the rod-segment could not be determined, the reason for this being indicated in the cultural experiments described later. In the sections of the reddish porous part of the middle lobe, rod-segments are also found in the interalveolar tissue, also small granules of the fungus. There are many granulomatous patches and in them are found areas of interlaced fibrils staining more or less deeply with Gram stain, also masses of fibrillar substance likewise staining blue. Small fragments of mycelium can be found in the exudate in the larger bronchioles over this area also. There occur in the larger bronchial tubes some sections of the tufts of the fungus: these stain deep blue and are very distinct and characteristic. Small scattered fragments of mycelium are found in many parts of the sections.

In the upper lobe no air-spaces remain, fibrous and granulomatous tissue alone are found with some blood-vessels and a few bronchial tubes; in these can be seen fragments of mycelium. The response to the extreme irritation of the parasite is the formation of new tissue, and the air-cells are destroyed. Apparently, the excessive new formation of tissue is unfavorable to the fungoid growth; it disappears. The parasite departs but the function of the lung is destroyed. Further invasion of new, softer tissues presumably occurs with similar results. This total lung destruction probably accounts for the marked short-windedness of most of the patients afflicted with this disease, indicated in physical signs by the so-called extreme fibrosis.

At what point the mycelium begins to form rod-segments is at present undetermined. They may form only when conditions become unfavorable for growth in any special region, or they may be formed in small numbers at all times. The former would be the more probable, however, in view of the larger number found at the place of invasion in the most recently infected point.

It is possible that the masses of mycelium, usually found in the sputum, are not capable of entering new tissues, in fact cannot cause infection; that is, that they must become rod-segments before really being dangerous to the system.

The peculiar manner in which the rod-segments surround the small blood-vessels is worthy of further study. Finding the interlaced mycelial threads apparently in blood-vessels was at first very puzzling, and only after the earlier stage of the process[3] was discovered did it seem possible that the fungus really was in the vessels.

SUMMARY

1. A large amount of granulomatous tissue takes the place of all air-sacs and small bronchioles in the final stage.
2. Marked absence of caseation and very little breaking down save in a pleural cavity.

The in many ways unexpected results obtained from the study of the tissues in this one case of primary streptothricosis of the lung make it most desirable that more should be critically examined to determine if the course of the pathologic changes is always the same or if noteworthy variation occurs.

CULTURAL AND SPUTUM EXPERIMENTS

To investigate more fully the character of the infectious agent responsible for the disease in these cases, a series of cultural experiments were made from Cases 9 and 17.

The contaminations unavoidable in sputum and the very poor growth of the organism on solid media made it impossible to obtain pure cultures without a much longer series of experiments than time allowed. The ordinary streak and plate methods are not suitable, since the secondary forms, growing freely, cover the surface before the streptothrix is started. Consequently bouillon was chosen and contaminating forms, chiefly staphylococci, disregarded. The small granules found in the sputum, consisting of tufts of mycelium, were carefully picked out either with a needle or pipette, washed thoroughly in repeated changes of sterile water and then either crushed or dropped whole into the tubes which were incubated at 37.5 C. and examined daily in hanging drops and smears, the latter stained with methylenblue by the Gram method.

In the hanging drop the growth of the organism is beautifully shown; in the earliest stage (twelve hours) it apparently consists of a few spores, and from them two or three delicate threads of mycelium; both stained and hanging drop mounts show this clearly. During the second, third and fourth days the small organism grows rapidly, becoming quite a mass of threads, radiating with more or less regularity from the center of growth. By the sixth day small but distinct granules can be seen in the bouillon; these are large enough to pick up and crush on slides to make smears. On agar the growth is but feeble, never in isolated masses, owing to the presence of more rapidly growing organisms, and not recognizable to the naked eye as separate masses. In hanging drops and smears it shows fragmented mycelium and rod-segments in abundance. The little tufts in the bouillon are tangled mycelium beset with many coccus-like spores, strongly Gram-positive.

In the early stages, up to the fourth day, the mycelium proved itself to be very resistant to stains of all kinds, only a few threads becoming colored even after prolonged treatment and none if merely the usual time was allowed. Parallel observations on the hanging drops showed the fungus to be present in abundance. Finally, by the time the small tufts became visible to the naked eye, on the fourth day, the usual staining properties began to appear and by the sixth day successful operations resulted from the standard method. At no time, however, was the organism acid-fast.

The application of the Gram stain to this organism discloses many points in the structure not shown by the ordinary stains. There is a great variation in the diameter of the different threads and as marked a difference in their staining qualities. Some are fine and hair-like, others coarse and thick. Many of the heavy ones stain a deep continuous blue, others are finely granular throughout, some segmented at regular intervals, like long strings of large bacilli, again like strings of streptococci, or in separate organisms, like bacilli; the rod-segments among those that take the Gram stain in whole or part are many that show only the counter stain and even that faintly; some are large, some small; the very young and the old degenerate threads. After becoming familiar with the organism it is easy to trace the same irregularity in staining in the tissues, though here the fragmentation is not a marked phase, save where the formation of rod-segments has occurred. The resistance to stain of the young mycelium also serves to explain the notable absence in the tissues of very young forms growing from the rod-segments. It is a well-known fact that microorganisms in tissues are more difficult to stain than in pus, sputum or cultures. It may be the difficulty in hardening the tissues rapidly enough to fix the organisms. In the case under consideration it would seem to be some qualities in the organisms themselves. Only as they grow old they lose the power and again fail to color typically. The exact conditions under which the rod-segments form are as yet not determined. It is evident that by no means does all mycelium fragment into them. Much of it dies, as evidenced by fine granulation and final lack of stain.

SUMMARY

1. The fungus is found to be markedly pleomorphic, occurring in (a) the classical grain or tuft, in culture and tissue, (b) fragmentations, bacillary, or even smaller, like granules, in tissues and discharges and some culture (solid) media. Very variable in size of mycelium.
2. The very young mycelium is resistant to all stains; the old threads likewise fail to stain.
3. In cultures and tufts the mycelial masses always show large numbers of small Gram-positive organisms (spores). Fine branching mycelium in the very early stage starts from these structures (demonstrated in hanging drops and smears). They are negative to Moeller's method for staining spores of ordinary fission fungi. They were not demonstrated in the tissues.
4. The active infectious agent in tissues is apparently the rod-segment.

To extend the study somewhat further a series of preparations was made from the sputum of many patients, tuberculous and others, as well as from Cases 9 and 17. This was to determine whether the Gram-picture was diagnostic of the disease and whether it appeared in sputum in the absence of microscopic tufts. No tuberculous sputum showed the same results. In Cases 9 and 17 particles of sputum chosen, carefully avoiding any macroscopic piece of the fungus, invariably gave rod-segments and fragmented mycelium. At one

---

[3] Pollack, Lohlein and Chiari report organisms in blood-vessels of lung and other tissues.

time when the pus appearance of the sputum was negative in Case 9 the rod-segments and mycelium showed abundantly by Gram stain.

Culture in bouillon always gave positive results in the absence of fungus in the sputum visible to the naked eye. By these two methods moreover, the Gram stain and bouillon culture, a case that was under observation for diagnosis was suspected and proved to be positive to culture. In a few days with severe coughing and profuse expectoration the macroscopic granules appeared, clinching the diagnosis.

If continued observations show these two methods to be absolutely trustworthy it will be possible to make an early and reliable diagnosis for this disease. The simplicity of a bouillon culture and hanging drop examination, together with some Gram-stained films, brings it within the reach of all who are near any sort of laboratory facilities.

RICKETS IN ITS EARLY STAGES AND BEST TREATMENT TO PREVENT DEFORMITIES *

J. W. COKENOWER, M.D.
DES MOINES, IA.

This subject has not been given much special attention recently, judging from a review of modern medical literature on diseases of children, and especially rickets, but all seemed to have been content with the fact that the disease was due to mal-assimilation with inevitable and unavoidable results and let it go at that.

Rickets is a disease of defective nutrition from mal-assimilation, augmented by the absence of sunshine and fresh air. Some authorities believe rickets due to toxins received by the child through special inheritage, while others contend the toxins are due to alimentation; however, let that be as it may, the disease is essentially a constitutional one and we must treat it as such.

The scrutinizing diagnostician will readily see that the disease is much more common than is generally supposed and will differentiate it by elimination from other diseases in children called something else. There are negatively etiologic factors which must be considered, among which are air, sunshine, hygienic environments, food and age. Like all diseases associated with impaired nutrition, it is less likely to occur among breast-fed children than among those who are deprived of their natural food. For the same reason it is more likely to occur in the latter part of the first year than in the early months, since in so many cases the breast-milk deteriorates in quality after the first six months of lactation and after one year still more so. On the other hand, premature weaning, or bottle-feeding, causes chronic indigestion, characterized by excessive acidity throughout the entire alimentary canal which overcharges the blood with acids and disturbs the ossification of the bones.

The disease exists most frequently in the temperate zone and in crowded unhygienic quarters of cities and especially large ones.

In addition to constitutional rachitic disturbances, the bone changes demand early attention, and marked changes are first noticed in the epiphyseals of the long bones most frequently at about the age of 6 months when the organic bone material exceeds the inorganic, and excessive ossification interferes with the growth of the child resulting in permanent hyperostosis.

The age limit is usually between 6 months and 3 years, and the early symptoms are many, among which, before the marked osseous change occurs, are constipation or diarrhea, gastro-intestinal disorders, night sweats, debility, inactivity, often fever, delayed dentition and rapid dental decay, but not typical Hutchinson teeth, nervousness and often convulsions, enlarged abdomen, large head, enlarged and tender epiphyses. All these symptoms may not be present, however, but there will be enough to enable one to make an easy and timely diagnosis, and as the disease is not necessarily a fatal one, it should be recognized sufficiently early to lessen the ravages and shorten the time of the disease so that no bone deformities may occur, and if they do, whether in the early deformity stage or not, there is no justifiable excuse for not preventing the deformity and correcting what exists.

The general treatment in the early stage should be constitutional in its fullest meaning, augmented by dietetic and hygienic measures, prevention of deformities, manipulation, mechanical and operative measures. Medicines are of minor importance compared to food, sunlight and fresh air; however, iron, arsenic, phosphorus, lactophosphate of lime and cod-liver oil may be given with advantage; but since the disease is self-limited, the object should be to tide the child over this period as quickly and safely as possible, remembering that during the softening stage of the bones faulty positions, muscular action, weight-bearing and atmospheric pressure are the main factors to observe in order to prevent deformities; and we should remember Wolf's law of development and equilibrium, that where there is any deviation from the normal perpendicular axis of the body, no matter in what part of the body the deviation or deformity exists, there will be a compensatory one and the entire body must pay the debt, and if this unnatural position be maintained long, the result will be permanent abnormal growth and deformity as in the case of torticollis, in which the bones of the head become flattened transversely, face distorted, eyes deficient and brain undeveloped; few such individuals live to be over 25 without becoming imbeciles.

The same principle is involved in the spine of the rachitic but to a much more serious degree, because nine out of ten such spinal curvatures are upper right dorsal, making convexity on right and concavity on left, causing the ribs to interfere with the normal functions of the organs of the thoracic cavity, especially the heart, which may result in organic lesions and a shortened life. One might thus specialize indefinitely, but generally speaking, rachitis affects the entire organism and produces marked changes in all bony and cartilaginous tissues by means of cell proliferation, and the atrophy is not due to halisteresis, but to the action of the osteoblasts and perforating canals, producing a deficiency of lime in the bones.

Hence, the proper preventive treatment during the stage of the softening of the bones should be to avoid weight-bearing on spine, arms or legs, and child kept on its back; for if it walks or sits, deformities are sure to occur; so the prone and supine recumbent positions

* Read in the Section on Diseases of Children of the American Medical Association, at the Sixty-Second Annual Session, held at Los Angeles, June, 1911.

must be maintained until constitutional and hygienic measures have conquered the disease.

It often occurs that cases are not seen by the physician until the disease has advanced far enough to present one or all of the inevitable deformities; but prompt action by an orthopedic surgeon should overcome such by means of gymnastics, manipulation, mechanical appliances, osteoclasis, osteotomy, tenotomy, myotomy, or tendon, nerve or muscle transplantation.

INTESTINAL PARASITES FOUND IN INDIVIDUALS RESIDING IN THE NORTHWEST

FREQUENT PRESENCE OF PROTOZOA IN PATIENTS WHO HAVE NEVER BEEN IN SOUTHERN COUNTRIES

W. E. SISTRUNK, M.D.
Assistant Pathologist, General Laboratory St. Mary's Hospital
ROCHESTER, MINN.

The feces of 145 patients were examined in this laboratory during the past four and one-half months. Thirty-five of these examinations were made relative to the function of the pancreas, or as controls; the remaining 110 in patients suffering with chronic diarrheas, anemias, or unexplainable abdominal conditions. In sixty-five of these 110 patients one or more of the following intestinal parasites were found; viz., *Amœba, Trichomonas intestinalis, Cercomonas intestinalis, Balantidium coli, Strongyloides intestinalis, Lamblia intestinalis, Ascaris lumbricoides or Trichocephalus dispar.* Thirty-four of the sixty-five patients, in whom these intestinal parasites were found, had never been south of the state of Iowa. Of this latter group, eleven were infected with *Entamœba tetragena* and one with *Entamœba histolytica.*

These findings are so contrary to the generally existing belief that such organisms are rarely seen in persons who have never lived in, nor visited, southern countries, that they have been considered sufficiently important to be brought to the attention of the medical profession. The series, though not a long one, seems sufficient to prove that the prevailing idea, regarding the geographical distribution of such organisms, is incorrect.

The following table shows the results of the findings:

Total number examined	145
Patients examined relative to pancreatic function or as controls, in whom no parasites were found	35
Patients examined suffering with chronic diarrhea, the passage of blood or mucus, anemia or obscure abdominal symptoms	110
Of these 110 patients, intestinal parasites were found in	65
Of these 110 patients, no intestinal parasites were found in	45
Patients showing parasites who had never been in the South or tropics	34
Patients showing parasites who had been in the South or tropics for a short time	7
Patients showing parasites who had lived in the South or tropics	15
Patients showing parasites of whom we have no clear history as to habitat (early cases with incomplete data)	9
Patients showing parasites who are known to have had diarrhea	42
Patients showing parasites who were examined on account of obscure abdominal symptoms, anemias or the passage of blood or mucus	9
Patients showing parasites who presented no symptoms of their presence	3
Patients showing parasites who presented no symptoms other than an abscess of the liver	1
Patients showing parasites who presented no symptoms other than anemia	1
Patients showing parasites in whom we had no history in regard to the above symptoms (early cases with incomplete data)	9

The following table shows the number of times each of the different parasites were seen and the number of time the various combinations of parasites were seen, i. e., in patients in whom more than one species was found.

Patients showing:

	No.
Entamœba tetragena	16
Entamœba coli	11
Entamœba histolytica	9
Small ameba and unclassified ameba	12
Trichomonas intestinalis	32
Cercomonas intestinalis	9
Lamblia intestinalis	4
Strongyloides intestinalis	1
Balantidium coli	1
Ascaris lumbricoides	1
Trichocephalus dispar	1

Patients showing the following combinations of parasites:

	No.
E. histolytica and *E tetragena*	1
E. histolytica and *Lamblia intestinalis*	1
E. histolytica and *Cercomonas intestinalis*	1
E. histolytica and *Strongyloides intestinalis*	1
E. tetragena and small ameba	1
E. tetragena and *Trichomonas intestinalis*	6
E. tetragena, E. coli, and *Trichomonas intestinalis*	2
E. tetragena, Cercomonas intestinalis and Trichomonas intestinalis	1
E. tetragena, E. coli, Cercomonas intestinalis and Trichomonas intestinalis	1
E. tetragena, Trichomonas intestinalis, Lamblia intestinalis and Ascaris lumbricoides	1
E. coli and *Trichomonas intestinalis*	3
E coli, small ameba, *Trichomonas intestinalis* and *Cercomonas intestinalis*	1
Trichomonas intestinalis and *Cercomonas intestinalis*	2
Trichomonas intestinalis and *Lamblia intestinalis*	1

The following table shows the number of times each species was found in the patients who had never been in the south or tropics:

	No.
E. coli	6
E. histolytica	1
E. tetragena	11
Trichomonas intestinalis	17
Balantidium coli	1
Lamblia intestinalis	3
Ascaris lumbricoides	1
Unclassified amebas	9
Cercomonas intestinalis	3

It will be seen that *Trichomonas intestinalis* was found more frequently than any other parasite—thirty-two times. *Entamœba tetragena,* a pathogenic ameba, recently separated from *E. histolytica* and *E. coli,* and which has been well described by Charles F. Craig,[1] was found in sixteen patients. Eleven of these are known never to have been in the South, a fact showing that this parasite—a pathogenic ameba—is frequently found in persons who have always lived in the middle Northwest.

A patient who had never been out of the state of Minnesota, and who had suffered with chronic diarrhea for eight or ten years, was found to be infected with four parasites; viz., *Entamœba tetragena, Lamblia intestinalis, Trichomonas intestinalis and Ascaris lumbricoides.* In another patient who had suffered for six months with diarrhea and who was out of Canada for the first time, *Entamœba tetragena and Trichomonas intestinalis* were found. The patient in whom *Balantidium coli* was found had suffered for twelve years with chronic diarrhea and showed a blood-picture of pernicious anemia. He had always lived in Minnesota and had never been in the South.

Eight of the nine patients showing *Entamœba histolytica* gave histories of having been in the South or tropics. The ninth patient had never before been out of the state of South Dakota. In twelve patients, amebas were found which I was unable to classify. Nearly all of these were seen at a date prior to the publication of Craig's paper, mentioned above—a communication which was of much value as an aid in differentiating the several species of amebas.

With two exceptions—*Ascaris lumbricoides* and *Trichocephalus dispar*—all of the parasites found belonged to the protozoa branch; this series of cases thus tending to show that in persons who have always lived in the middle Northwest, protozoa are more frequently found than other intestinal parasites.

---

[1] Craig, C. F.: Arch. Int. Med., March 15, 1911, vii, No. 3.

While this work was being done, the pus from the mouths of twelve patients suffering with mild and well-marked cases of purulent gingivitis was examined. In six of these, *Entamœba buccalis* was found and in two, in addition to the amebas, a species of *Trichomonas* was found. Four of these six patients had never been in the South.[2]

Authors differ in their statements relative to the pathogenic features of protozoa. I do not wish to enter into a discussion of these differences of opinion, except in so far as it is necessary to make clear my own views as to why they exist. The frequency with which authors who have done no particular work in this field have copied from others may partly explain these differences. In such instances varying statements are found by them, in the different articles on the subject, and, being unable to throw the weight of their own opinions either one way or the other, through lack of personal work, they are compelled to make indefinite statements regarding the pathogenicity of the parasites under discussion. Such statements are mere conclusions, drawn from the assertions of others, and serve only to complicate matters by adding another indefinite chapter to further confuse subsequent authors. Had all of the published articles pertaining to animal parasites been written by men whose statements were based on their own work, we would, no doubt, by this time possess a far clearer conception of their pathogenic qualities.

It seems that either a negative or a positive statement, made without qualification, that protozoa are pathogenic, would be wrong. There is no doubt that they are seen in the feces of persons who show no symptoms of their presence. However, in such individuals they are generally *found in comparatively small numbers. Their* mere presence, under such conditions, does not prove that they do not possess pathogenic qualities which, perhaps under different conditions, would become apparent. My own work has certainly strongly indicated the existence of such properties.

Bacteriologists have shown that diphtheria bacilli and pneumococci may frequently be found in the throats of healthy individuals; that typhoid bacilli may be harbored, and transmitted to others, by persons who have never had a recognized attack of typhoid fever. A parallel condition may also be seen in at least one protozoan infection, for it has been long known that all that was necessary to produce an acute outbreak of malarial fever in some apparently healthy southern residents was to send them to the mountains. The *Plasmodium malariæ*, which they had harbored, under the condition in which their host had lived, had not possessed sufficient pathogenic qualities to cause the manifestation of symptoms, but a climatic change, alone, in such cases has been all that was necessary to cause them to show pronounced pathogenicity.

Individual resistance, no doubt, plays an important rôle in the explanation of the fact that the parasites may be found in persons who show no symptoms. Any of us are liable to infection; having acquired such, we may show symptoms immediately or may harbor the parasite, without symptoms, for an indefinite period. This is probably due to the fact that the organism is unable to do more than barely exist and reproduce itself in its host. The cause of this inability, as already mentioned, may be due to high resistance on the part of the host or, as suggested by Musgrave and Clegg, to the non-establishment, on the part of the parasite, of a satisfactory symbiosis with some bacterium or other parasite; a condition which has been found necessary for the growth of these organisms in culture media.

An example of this apparent resistance may be cited in individuals with amebic infections, who have recovered from a typical chronic dysentery. Such patients will often be found to harbor amebas for years and during this period may show no symptoms beyond an occasional short recurrence of the dysentery. Some do not show even this, but, if left untreated, are liable later to develop digestive disturbances and obscure pains along the colon.

Amebas in persons living in cold climates do not, as a rule, produce disturbances so serious as those seen in persons in tropical countries. The patients seen here were generally having from three to eight watery movements a day, with some mucus, but, as a rule, no blood. This, however, is not strange, for we know that persons with this disease who will not improve in tropical countries may receive great benefit by moving to cold climates; also that persons who have suffered for years with this condition generally have less trouble in winter than in summer.

Two reasons probably account for these infections being so frequently overlooked: (1) the fact that it is commonly believed that these parasites are not found in persons living in this climate; their presence not being suspected, examinations for them are not often made; (2) the fact that stools are not always examined by a method by which this group of organisms may be recognized.

The technic by which our examinations have been made is not new but will be described in detail, with the hope that it may assist some who care to go further in this work. It is the same as that which I have used for some years, while doing similar work in Louisiana, and it has been found more satisfactory than any of the other methods.

The patients are given from ½ to 1 ounce of Epsom salts before breakfast on the morning selected for the examination. After breakfast they go to the laboratory where they wait until they desire to have a bowel movement. They are then sent to a toilet where, after voiding urine, they defecate in a commode. This specimen is examined at once. A small drop of the liquid feces, or a small piece of mucus, if obtainable, is placed on a slide, covered with a cover glass and examined on a warm stage, using a 4 mm. (1/6 inch) objective. (These warm stages are easily made from almost any metal, such as copper, zinc, tin, etc., which will transmit heat and is soft enough to permit being cut into the desired shape with shears. They may be used on the ordinary stage of any microscope and are kept warm by means of a small flame from an alcohol lamp or a gas burner.) If the first movement is too solid to permit the making of a satisfactory examination without being diluted, it will be found necessary to have the patient wait for a second or third movement, these being collected in the same manner. The last stools passed will, at times, be found so watery that they are almost useless for examination. Those passed between the first movement and these watery movements will generally be found most suitable. It is best to obtain two or three movements and examine several cover-glass preparations from each.

---

[2] These mouth cases are not included in the 145 cases on which this article was written.

Many infected cases are overlooked in both the North and South, through the fact that a technic similar to the above is not used. Patients are frequently seen here who have passed through numerous competent hands, but in whom parasites have been overlooked. In nearly all of these cases, this was accounted for through the fact that they had been asked to send or bring a specimen for examination. The same mistake occurs in hospital work. In these, specimens are sent to the laboratory where they may remain for several hours before being examined. A report based on an examination made after such a delay is valueless in eliminating protozoa. In some such instances they might be found, but in many cases they would not, for it is almost impossible to recognize and differentiate these organisms after their characteristic motility has been lost.

I have done nothing toward working out the sources through which these infections may have been acquired. It is probable that in the summer amebas may exist in northern water-supplies and that infections occur as in other climates. It is also possible that some infections may be acquired through uncooked vegetables and fruit which have been raised in the South and shipped moist to the northern markets or by direct transmission through previously infected persons.

It seems as though the geographical distribution of these organisms is greater than is generally supposed, and it is probable that careful examinations will show that they frequently exist in countries now thought to be almost free from them.

Many points regarding the life habits of these parasites, their methods of reproduction and the manner in which they cause symptoms—whether through mechanical irritation or toxins—remain to be cleared up. A great field is open to workers who wish to devote their time to the study of some of the problems along this line.

CONCLUSIONS

1. The common belief that intestinal protozoa are seen only in persons who have lived in or visited the South or tropics is erroneous. They are frequently found in persons who have always lived in the North and, when seen in great numbers, are generally found associated with chronic diarrheas, obscure abdominal pains or anemias.

2. Many infected cases are probably overlooked; first because parasites are not suspected and, hence, not looked for; second, because poor technic is used in examining the specimens.

3. Of the animal parasites found in patients who had never been in the South, protozoa were more frequently seen than all the other varieties.

4. *Entamœba tetragena*—a pathogenic ameba recently separated from *E. histolytica* and *E. coli* by Viereck—was often found in persons who had never been in the South. It is probable that this organism accounts for many of the chronic diarrheas seen in persons living in this part of the United States.

I wish to thank Dr. Louis B. Wilson for his kindness in having examined with me many of the specimens in which the diagnosis of the particular species of organism was questionable.

Galen on Commercialism.—"The good physician should practice with disinterestedness, not for money but for the good of humanity. It is not possible to covet riches and at the same time to cultivate worthily medicine, that art so noble; if a man devote himself ardently to one, he will certainly neglect the other."

THE RELATIVE VALUE OF PHYSICAL AND FUNCTIONAL SIGNS IN THE MANAGEMENT OF FAILING CIRCULATION *

EMILE SCHMOLL, M.D.
SAN FRANCISCO

The impetus given to the study of pathologic anatomy by the discoveries and theories of Virchow and his pupils influenced clinical medicine so greatly that from that time most of our efforts have been directed toward arriving at a clear diagnosis of the anatomic changes wrought by disease.

Our clinical examination attempts to determine the changes in size and configuration of organs, and by correlating these data with the facts revealed in the history of the patient, we try to arrive at an anatomically correct diagnosis.

Such a conception of our diagnostic aim, and the accompanying neglect of the problems of functional disturbance, could lead only to the therapeutic nihilism which we know followed the triumph of pathologic anatomy. It was seen then that these structural changes could not be cleared away by treatment, except in the few cases in which our remedy deals directly with the cause of the disease. Even surgery, with all its advances, is generally called on to remove the results and not the cause of disease. We must recognize clearly, then, that in the great majority of cases our treatment does not pretend to alter the anatomic changes, but endeavors only to restore the balance of function.

Intelligent treatment, then, should be preceded by an accurate functional diagnosis, which must include a consideration not only of the changes in the organ primarily affected, but of the disturbances set up in the whole body by the failure of that organ to do its share of work. Our neglect of this functional problem has thrown our dependence entirely on the results of our physical examination, so that our conclusions stand or fall with accuracy of the methods employed.

Nowhere in the realm of physical diagnosis can we find more varied or more accurate methods than those which we now use in studying the heart, and their accuracy is due largely to the innumerable autopsy records which have been and can still be of tremendous importance in controlling our findings. It must be remembered, however, that this experience was gained almost entirely in cases of advanced heart disease from which the patient had died as the result of a failure in compensation. Our methods have shown such pronounced and unmistakable changes in these hearts that we now try to discover the beginnings of organic heart disease, or to exclude functional trouble simply by demonstrating slight deviations from our accepted standards. The recent advances in our knowledge of the intricate disturbances that may take place in the heart-muscle have imposed on us the necessity for recognizing these changes also in their incipiency.

Any one who is constantly being called on to say whether a certain pain is anginoid or due to a coronary sclerosis, or whether a little shortness of breath associated with occasional extrasystoles is due to a beginning myodegeneration or to a high diaphragm, will appreciate an inquiry into the accuracy of our methods. After an extended study of these borderline cases, it seems to me that the great majority of physicians overestimate the value of physical diagnosis and pay too little attention to the condition of the other organs whose welfare depends on an intact circulation. They are too prone to diagnose dilatation or hypertrophy whenever they find an increase in the heart dulness, and the patient is made miserable at the prospect of an incurable disease. Credit should here be given to Romberg who was one of the first to deplore this tendency.

* Read in the Section on Pharmacology and Therapeutics of the American Medical Association, at the Sixty-Second Annual Session, held at Los Angeles, June, 1911.

We were inclined to believe implicitly in the accuracy of percussion in outlining the heart until Moritz' orthodiagraph enabled us to check our figures, and showed that good men can often make mistakes of 4 to 5 cm. on either side of the heart. Fortunately, we now possess a number of methods, foremost among which I would mention Goldscheider's "threshold percussion" which enables us to outline the heart and large vessels with an error of 0.5 to 0.75 cm. on either side. But even after securing this outline and finding it so nearly in accordance with the orthodiagram, we must still consider the following sources of error:

1. Changes in size and position produced by systole and diastole.
2. Changes in the size of the heart due to respiration.
3. Changes in the size of the heart due to pathologic changes within the chest.
4. Changes in the size of the heart produced by pathologic conditions in the abdomen.
5. Changes in the size of the heart depending on the general configuration of the body.

The left border of the heart is hard to locate for several reasons. For instance, since percussion can be directed only perpendicularly to the surface, the curvature of the chest near the apex causes us to encounter the heart-dulness considerably outside the point where it would appear if we could percuss strictly anterior-posteriorly. Thus, the heart appears to be larger and the error varies according to the degree of curvature. In the emphysematous it may be quite considerable. Palpation should help us most at this point, but unfortunately, the apex-beat is liable to be very diffuse in just those cases in which we must differentiate between beginning dilatation and a neurosis. The apex may lift the chest-wall so widely that the outer border of the pulsation will be sometimes several centimeters outside the real heart-border which is identical with the point of maximum impulse, if that can be made out. Again, the intensity of this impulse is often taken as an indication of the force of the heart contraction, while it really depends largely on the position of the heart within the chest.

The orthodiagraph may also fail us at the apex, as the shadow of the heart is likely to be buried here in that of the diaphragm. The efforts of Moritz to overcome this difficulty do not seem to me to have succeeded sufficiently to warrant us in following his deductions.

The orthodiagram gives us a silhouette smaller than the actual diameter of the heart, owing to its oblique position in the chest. The amount of rotation varies but slightly, still, if the greater diameter of the heart becomes more nearly parallel to the anterior chest-wall, the error introduced might be enough to incline our judgment to the diagnosis of an enlarged heart.

The outline of the heart changes with each systole and diastole, especially on the left side where the ventricle diminishes in size 2 to 3 cm. with systole. The right border moves much less as it is formed by the more feeble right auricle. These changes do not appear on percussion, since only the diastolic outline is obtained, but they are seen very plainly with the orthodiagraph.

Respiration affects the right side of the heart markedly in two ways. The negative pressure during inspiration aspirates the blood into the right auricle, while at the same time the diaphragm expresses blood from the abdomen into the thorax. Then expiration reduces the size of the right auricle.

The change in position of the heart which occurs during respiration has a marked influence on the apparent transverse diameter. The base of the heart is more or less fixed by the great vessels, while the apex follows the diaphragm up and down. When it is down, the heart is more nearly vertical in position and the transverse diameter appears to be lessened. At the same time, there is a rotation which further reduces the width of the silhouette. An unequal inflation of the lungs will displace the heart from its position in the mediastinum, and quite frequently this is mistaken for a dilatation.

Foremost among the pathologic conditions of the chest which must be studied in this connection is kyphoscoliosis. We have all seen the bizarre distortions of the heart outline which are frequently met with in this condition. Doubt often remains as to whether there is a dilatation, especially on the right side, or whether the increased dulness is due purely to a change in position.

An apparent increase in the transverse diameter of the heart is seen occasionally in anemia and chlorosis, in which it is due to an atelectasis of the left lung which allows the heart to be pushed against the anterior chest-wall. The diagnosis of dilatation appears even more justifiable when a mitral murmur is present, but this error may be avoided by determining the position of the diaphragm.

The base of the heart may be lowered by the lengthening of the aorta which takes place in some cases of aneurysm and aortic sclerosis, and a dilatation of the heart chambers is diagnosed to explain the perplexing circulatory symptoms.

There are a number of abdominal conditions which in their symptomatology may closely imitate cardiac disease. They have this in common, that the abdominal cavity is distended, the diaphragm is pushed upward and the heart is forced to take a more nearly horizontal position. This can be seen plainly in ascites or in large ovarian cysts. Such an anomalous position, coupled with occasional irregularities, is frequently seen with uterine myomata. Here, besides the mechanical disturbances, there is liable to be a profound anemia due to constant hemorrhage. A mitral murmur, then, with an apparent increase in the transverse diameter of the heart, and the irregularities seem to render a diagnosis of heart disease most probable, but the complete disappearance of all signs and symptoms on removal of the tumor shows conclusively that the disturbance was purely functional. The same explanation applies to the so-called hypertrophy of pregnancy. Here also we have learned that the apparent heart changes are due to the rise of the pregnant uterus and not to any changes in the heart itself.

A distention of the fundus of the stomach, with its attendant elevation of the left diaphragm, is one of the most common causes of heart symptoms. The numerous extrasystoles, anginoid pains and widening of the heart dulness frequently induce the beginner to diagnose serious heart trouble with its bad prognosis. The determination of the position of the diaphragm enables us to recognize this condition, and relief from all symptoms may be secured in a few days with a suitable diet.

Before deciding on the presence of the dilatation we must compare the relations of the heart dulness to the whole body. The neglect of this important rule has led to the theory of cardiac hypertrophy at puberty. The thorax lags behind the heart in its development at this time, so that the heart becomes relatively large; the apex beat can often be felt below the fifth interspace outside the mammillary line, and the impulse is very heaving on account of the thinness of the chest-wall. The coexistence of these findings with a juvenile arrhythmia so frequently seen is strongly suggestive of myocardial disease, but the whole condition clears up with the development of the thorax.

The theory of constitutional heart weakness worked out by Kraus is of the greatest importance in this connection. In my experience this condition has been almost invariably associated with the general asthenia described by Stiller. Characteristic of this habitus is the long, narrow thorax with the lower ribs descending almost vertically, and a very narrow epigastric angle. The abdominal wall is generally relaxed and all the viscera are ptotic. The diaphragm is also lowered so that the shadows of the tenth and even the eleventh ribs may appear above it. The influence of this position on the circulation has been shown so masterfully by Wenckebach that I shall merely refer here to his paper. The loss of apical support leaves the heart hanging from its basal attachments, and the transverse diameter may be diminished markedly by the more nearly vertical position. Under these conditions, it is almost impossible to be sure of a transverse enlargement, and I can remember many cases in which I hesitated for some time to diagnose a heart lesion.

In obesity, not only is the diaphragm pushed up, with an apparent increase in the transverse diameter of the heart, but the uncertainties of percussion are enhanced by the greater thickness of the chest-wall.

Thus we see that any attempt to found the differential diagnosis between functional and beginning organic heart disease on a questionable enlargement is pseudoscientific. Since the methods at our disposal are inaccurate and do not furnish sufficient data in themselves, we must welcome two more factors which can be of great service in reaching a conclusion—the questions of function and of probable etiology.

By far the most important evidence in this problem is to be derived from a study of the circulatory changes throughout the body, and little signs of failure can be found, in this way, long before the most careful methods can detect anything wrong with the central organ. A large soft liver associated with severe flatulence and distention of the stomach are usually the first tidings of a break in compensation, and edema of the ankles soon completes the picture of right-sided failure. Sometimes this well-known syndrome is preceded a few days by a sudden gain in weight due to interstitial edema without any other objective sign. This point, while well known, does not seem to have received the attention it deserves, but I would emphasize it particularly as it has proved invaluable in my hands.

Pulmonary symptoms are generally the earliest signs of embarrassment of the left side of the heart. Attacks of dry cough, ending perhaps in the expectoration of a little bloody serum, often precede the final attack of pulmonary edema by several years. In the more chronic cases, atelectatic patches with fine râles at the bases of the lungs point to a deficiency of the left ventricle. A decrease in the usual large amount of urine is always highly suspicious, and a balance between intake and output will prove a definite retention of fluids.

A factor of the greatest importance and one that must not be overlooked in the differentiation between functional and organic heart trouble, especially in patients over 40 years of age, is the presence of arteriosclerotic changes in the aorta and large vessels. As aids in making our decision may be mentioned the ringing, high-pitched second aortic sound, unequal elevation of the subclavian arteries, pupillary changes and the characteristic radiogram.

The smallest symptom raises our suspicions when coupled with slight rheumatic disturbances. In the absence of any signs of valvular disease, we think of adherent pericardium or a mitral stenosis unaccompanied by a murmur. Especially when there is a history of chorea do we think of rheumatic myocarditis with its nodules in the Tawara system.

A positive Wassermann reaction has sometimes changed my convictions about a doubtful case. I remember particularly a patient whose ailment had for years been treated as functional. This woman, aged 42, had recurring attacks when for days and weeks the normal rhythm would be interrupted by numerous very painful extrasystoles. When every method of treatment had been exhausted in vain, the positive Wassermann was discovered and she became entirely well under specific treatment.

An enlarged thyroid is often overlooked as the cause of severe heart trouble. I refer not only to the cases of hyperthyroidism, but to those cases in which an ordinary goiter located under the sternum interferes with a venous back-flow to such an extent as finally to produce organic disease.

When we come to the treatment of these diseases, we must study still further the functional side of the problem. Leaking valves and an increase in the size of the heart do not call for medication, so long as the heart muscle compensates and maintains a good circulation. It is only when the signs of insufficient circulation begin to appear in various parts of the body that we must interfere.

For purpose of treatment, heart diseases may be divided into two groups; the first includes all cases of rheumatic origin and the other is characterized by a primary progressive disease of the arteries. The common signs of failure in the first group are: râles at the base of the lung posteriorly, a gain in weight, enlargement of the liver and edema of the ankles. It is in these cases that digitalis earns its great popularity, and we must judge of the rate of improvement by the subsidence of the symptoms just described and not by any diminution in the size of the heart. In my experience the finding of narrowed heart dulness is generally the result of autosuggestion. The disappearance of edema, an increase in the total amount of urine, and a slowing of the heart-rate are much more reliable gauges of the heart's condition.

The arterial degenerations of the second group often lead to conditions closely resembling those of the first group. Here, too, there may be a leaking aortic or mitral valve with dilatation and hypertrophy of either ventricle, but the treatment must be along different lines. Not only is the heart diseased in these cases, but there is a deterioration of almost every vital organ following years of deficient blood-supply. This is particularly true of the kidney and the symptoms in these cases are frequently those of slight uremia. The arterial origin of the apparent heart disease is betrayed by the estimate the value of physical diagnosis and pay too little attention to the condition of the other organs whose welfare depends on an intact circulation. They are too prone to diagnose dilatation or hypertrophy whenever they find an increase in the heart dulness, and the patient is made miserable at the prospect of an incurable disease. Credit should here be given to Romberg who was one of the first to deplore this tendency.

We were inclined to believe implicitly in the accuracy of percussion in outlining the heart until Moritz' orthodiagraph enabled us to check our figures, and showed that good men can often make mistakes of 4 to 5 cm. on either side of the heart. Fortunately, we now possess a number of methods, foremost among which I would mention Goldscheider's "threshold percussion" which enables us to outline the heart and large vessels with an error of 0.5 to 0.75 cm. on either side. But even after securing this outline and finding it so nearly in accordance with the orthodiagram, we must still consider the following sources of error:

1. Changes in size and position produced by systole and diastole.
2. Changes in the size of the heart due to respiration.
3. Changes in the size of the heart due to pathologic changes within the chest.
4. Changes in the size of the heart produced by pathologic conditions in the abdomen.
5. Changes in the size of the heart depending on the general configuration of the body.

The left border of the heart is hard to locate for several reasons. For instance, since percussion can be directed only perpendicularly to the surface, the curvature of the chest near the apex causes us to encounter the heart-dulness considerably outside the point where it would appear if we could percuss strictly anterior-posteriorly. Thus, the heart appears to be larger and the error varies according to the degree of curvature. In the emphysematous it may be quite considerable. Palpation should help us most at this point, but unfortunately, the apex-beat is liable to be very diffuse in just those cases in which we must differentiate between beginning dilatation and a neurosis. The apex may lift the chest-wall so widely that the outer border of the pulsation will be sometimes several centimeters outside the real heart-border which is identical with the point of maximum impulse, if that can be made out. Again, the intensity of this impulse is often taken as an indication of the force of the heart contraction, while it really depends largely on the position of the heart within the chest.

The orthodiagraph may also fail us at the apex, as the shadow of the heart is likely to be buried here in that of the diaphragm. The efforts of Moritz to overcome this difficulty do not seem to me to have succeeded sufficiently to warrant us in following his deductions.

The orthodiagram gives us a silhouette smaller than the actual diameter of the heart, owing to its oblique position in the chest. The amount of rotation varies but slightly, still, if the greater diameter of the heart becomes more nearly parallel to the anterior chest-wall, the error introduced might be enough to incline our judgment to the diagnosis of an enlarged heart.

The arterial degenerations of the second group often lead to conditions closely resembling those of the first group. Here, too, there may be a leaking aortic or mitral valve with dilatation and hypertrophy of either ventricle, but the treatment must be along different lines. Not only is the heart diseased in these cases, but there is a deterioration of almost every vital organ following years of deficient blood-supply. This is particularly true of the kidney and the symptoms in these cases are frequently those of slight uremia. The arterial origin of the apparent heart disease is betrayed by the high blood-pressure, headache, gastro-intestinal symptoms and particularly attacks of nocturnal asthma.

Digitalis will only aggravate such cases, and treatment must be directed toward relieving the kidney. Most important then is a salt-free low protein diet, supplemented by the free use of diuretics.

Above all, we must remember that we are dealing not with diseased organs but with sick people, and in studying the physical changes in one part, we must not overlook the secondary changes throughout the whole body.

THE RELATION OF CARDIAC IRREGULARITIES TO TREATMENT *

ALBION WALTER HEWLETT, M.D.
ANN ARBOR, MICH.

In the treatment of heart disease the interest centers chiefly on the symptoms of broken compensation, and to a lesser extent on sensations referable to the heart. Changes in cardiac rate or rhythm may influence either of these. A feeling of palpitation sometimes accompanies tachycardias and marked irregularities; and sensations of heart-jumps or heart-stops are common to those who have extrasystoles. Even though the trouble seems to be nervous, and the general circulation is well maintained, nevertheless, so long as the rate or rhythm of the heart is disturbed a condition is present which fixes the attention of an apprehensive patient and interferes with his recovery.

EFFECTS OF DISTURBED RHYTHM ON THE BLOOD-FLOW

Variations in the cardiac rhythm may, moreover, actually impede the circulation. There is an optimum range for the heart-rate which permits this organ to act at the best advantage, and rates which are much above and much below this are mechanically disadvantageous. Very fast rates interfere with the filling of the heart during diastole, and slow rates are not compensated for by an increased output at each systole. Henderson[1] has shown that for the normal dog the total output from the heart does not increase proportionately to increases of rate above the normal. The shortening of diastole lessens the filling of the heart and while the total output increases fairly rapidly with increases of rate up to 120 beats per minute, increases in rate beyond this are accompanied by rapidly diminishing increases in total output, until beyond still higher rates (150 to 220) there is an actual diminution in the total output. On the other hand, rates below 80 per minute are accompanied by a reduced output which is almost proportional to the reduction in rate. This applies both to continuously rapid and continuously slow rates as well as to occasional variations in rhythm. A missed beat, for example, is not entirely compensated for by an increased expulsion of blood at the next systole, while a series of very rapid contractions are apt to be ineffectual.

Variations in rhythm may also be mechanically disadvantageous for the reason that the auricles and ventricles contract simultaneously. During such simultaneous contractions the auricles cannot empty themselves into the ventricles, but send a reflux wave back into the veins, opposing the flow in these vessels. In paroxysmal tachycardia the heart action may be so rapid that the ventricular systoles coincide with the auricular systoles of the following heart-cycle (Wenckebach's critical heart rate).[2] The same thing may occur when the conduction time between auricles and ventricles is greatly slowed, or when extrasystoles, originating in the ventricles, cause these chambers to contract simultaneously with the auricles. In such cases the auricular contractions oppose the venous flow. In auricular fibrillation the auricles are motionless from the mechanical point of view, and while the mechanical effect of auricular contractions has probably been overrated,[3] still in mitral stenosis the auricles seem to be a factor in maintaining compensation,[4] and their loss of coordinate contractile power must be mechanically disadvantageous. Finally, irregularities may be disadvantageous for the reason that the ventricles contract in an abnormal manner. Electrocardiograms have shown the ventricular extrasystoles commonly pursue an abnormal path in spreading over the ventricular muscle and such extrasystoles frequently produce pulses much smaller than one would anticipate from the duration of the preceding diastoles.

For these reasons it is evident that cardiac irregularities deserve more attention than has usually been accorded to them in the treatment of heart disease. The same heart muscle which could carry on the circulation if it contracted regularly and at a proper rate would be insufficient when contracting irregularly, too frequently, or too slowly. This seems to be the explanation of the signs of insufficiency which may occur during prolonged attacks of paroxysmal tachycardia. A similar insufficiency may develop during paroxysms of auricular fibrillation[5] and disappear when the latter pass off. The occurrence of very numerous extrasystoles may also be accompanied by increased symptoms of insufficiency. In these cases the potential capabilities of the heart probably remain unchanged, but the wasteful manner in which the muscle is made to contract causes the insufficiency.

SCOPE OF DISCUSSION

In discussing the relation of cardiac irregularities to treatment we shall limit ourselves to the commoner and more important forms and shall discuss the relation of drugs both in causing and alleviating these. Unfortunately, it is difficult to transfer the results of animal experiments to man. In the first place, relatively large doses of drugs are commonly used on animals, and "acute" experiments are not strictly comparable to the common therapeutic practice of giving small doses of a drug over a prolonged period of time. In the second place, we are usually dealing, in clinical cases, with an abnormal heart muscle which may be sensitive to small doses or insensitive to relatively large doses of a drug. For these reasons the results of animal experiments must be constantly checked by observations at the bedside and these latter need the most careful scrutiny in order to be reliable.

VAGUS IRREGULARITIES

The various forms of cardiac irregularities have but little in common beyond the fact that some seem to depend on changes in the heart muscle and others on nervous influences. They must, therefore, be taken up separately in their relations to treatment.

The irregularities which are due to unusually labile vagus control of the heart rate occur most frequently in young persons, in neurotic individuals, and after infectious diseases. They are favored by the use of digitalis.[6] As these irregularities have no significance beyond indicating an unusually active vagus control they do not require treatment and the patient or relatives, if alarmed, should be reassured. Large doses of atropin will cause their complete or partial disappearance, with a simultaneous increase in heart-rate, but the effect is usually only temporary and the drug is not indicated for therapeutic purposes.

HEART-BLOCK

Partial block, or an interruption of some but not of all stimuli traveling from the auricles to the ventricles, has been frequently produced in susceptible individuals by drugs of the digitalis series, viz., digitalis, strophanthin, squills. For example, in a patient recently at the University Hospital the intravenous injection of 1 mg. of strophanthin caused a previously regular heart to show an immediate partial block, with one ventricular to two or three auricular beats.[7] The mechanism by which digitalis causes partial block in man is not entirely understood. Since it stimulates the vagus nerve, and such stimulation may cause partial block, one may assume that we are dealing with a pure vagus effect. In the majority of cases, however, a simultaneous slowing of the auricles has not occurred, which would seem to indicate that in these hearts the conduction apparatus between auricles and ventricles was abnormally sensitive to digitalis. When the conduction time is already reduced, as shown by a lengthened *a-c* interval on the venous pulse, one should be especially cautious in the use of digitalis.

In the treatment of a patient with heart-block, whether partial or complete, our first endeavor should be to find and to remove the cause. If the patient has been taking large doses of digitalis or allied drugs these should be temporarily discontinued. Of the various lesions which may effect the bundle of His, such as tumors, acute inflammations, fibrous changes and syphilitic processes, the latter alone are directly amenable to drugs, and in the presence of a positive Wassermann reaction, antisyphilitic treatment is urgently indicated. Improvement following such treatment has been recorded on several occasions.[8] It should be remembered, however, that blocks may disappear spontaneously, especially when they occur in connection with acute infectious diseases.[9]

When a complete block does not disappear either spontaneously or as a result of treatment, the circulation may be improved, theoretically at least, either by increasing the abnormally slow ventricular rate, or by increasing the efficiency of the individual ventricular contractions. It is known that toxic doses of digitalis may increase the ventricular rate so markedly that it exceeds the auricular rate,[10] and the question naturally arises whether smaller doses might not increase it sufficiently to be of therapeutic value in complete block. Few deliberate attempts[11] to accomplish this are on record, and these have not given striking results. In a case which I reported with Dr. Barringer,[12] large doses of digitalis did not increase the ventricular rate, but they did cause ventricular extrasystoles; and it is possible that the rapid ventricular rate of experimental digitalis poisoning is due to a succession of extrasystoles. If this be true, we can expect no beneficial results to follow an attempt to increase the ventricular rate in patients with complete block by pushing digitalis medication. On the other hand, the slow ventricular action is no contraindication to the use of this class of drugs, for the latter do not slow automatically beating ventricles. The good results which sometimes follow the use of digitalis in complete block is probably explainable by its effect on the efficiency of the individual muscular contractions.

In partial heart-block digitalis should be used very cautiously if at all, because it tends to increase the block, and this may more than compensate for any beneficial effect it has on the force of the ventricular contractions. In some cases of partial block the irregularity may be overcome by the use of atropin injections. I have seen one case in which atropin stopped the block, but in several other cases the injection of atropin was ineffective.[7]

EXTRASYSTOLES

By extrasystoles we mean cardiac contractions which originate in parts of the heart muscle other than those normally governing its rate. These seem to be due either to abnormal stimuli or to a local condition of increased muscular irritability. Extrasystoles are extremely capricious in their appearance and this makes it very difficult to demonstrate the effects of drugs either as causative or curative factors. In elderly persons they are less apt to disappear completely than in young individuals; probably because in the former they are more often due to chronic myocardial changes, while in the latter they are often due to acute changes or to toxic agents. The abuse of tobacco is generally recognized as an important etiologic factor and I have seen several cases in which extrasystoles disappeared in young individuals after discontinuing tobacco. Tea, coffee, or any condition which increases the general nervousness of an individual may also perhaps increase the irritability of the heart muscle and the tendency to extrasystoles. In large doses digitalis is capable of causing extrasystoles. In smaller doses its effect is not so certain. Wenckebach believes that experimental evidence favors the view that small doses of digitalis lessens cardiac irritability and he has seen extrasystoles disappear in patients to whom small doses of the drug were given. Owing to the capriciousness of extrasystoles I am inclined with Cushny to doubt a direct relation between the drug and the disappearance of extrasystoles and have never been able to convince myself that this effect was produced independently of its effect in lessening the cardiac insufficiency. In two patients I have recorded the occurrence of extrasystoles on long, continuous tracings before and after intravenous injections of 0.001 strophanthin, but I was not able to demonstrate any definite effect of the drug on the irregularity.

Occasional extrasystoles which are not accompanied by evidence of broken compensation or by nervous symptoms do not, in themselves, require treatment. Possibly drugs will be found which will lessen an abnormal local irritability of the heart muscle. At present, however, we must treat extrasystoles on general principles. In very nervous individuals, the treatment should be directed toward relieving the nervousness. Tea, coffee, and especially tobacco, should be forbidden. Attention should also be directed toward factors which might damage the heart muscle, such as acute or chronic infections, arteriosclerosis, etc. High blood-pressure and cardiac dilatation probably serve as abnormal stimuli to the heart muscle, and improvement in the extrasystoles may occur when these are lessened. On the whole, our treatment of extrasystoles is very unsatisfactory, and, in many cases, they persist in spite of all our efforts.

AURICULAR FIBRILLATION

Auricular fibrillation, which is the most important and most serious form of cardiac irregularity, is characterized clinically by an extreme degree of ventricular irregularity and by an absence of gross auricular contractions. Frequently, it begins as paroxysms of greater or lesser duration which tend later to become permanent. Auricular fibrillation has many points in common with auricular extrasystoles, for both seem to be due to an abnormally irritable condition of the auricular muscle. Both are sometimes seen in the same patient and transitions have been described.[13] While organic myocardial changes are usually assumed to be responsible for auricular fibrillation, there is evidence that nervous or toxic influences may precipitate attacks of this irregularity in susceptible individuals. Cushny and Mackenzie cite cases of this sort from digitalis, and I have reported two cases to which this explanation seems possible, although, in the reports, such a possibility was not discussed. In one, a single injection of strophanthin converted a rapid and regular pulse [auricular tachycardia (?)] into fibrillation which remained permanent.[14] In the other, a case of complete heart-block, large doses of digitalis twice caused the auricular waves to disappear from the tracings and on both occasions they reappeared when the digitalis was discontinued.[12] Attacks of auricular fibrillation may be first seen after operations,[5] and it is possible that changes in the heart muscle produced by the anesthetic may be responsible for their occurrence. Finally, auricular fibrillation is very common in the late stages of exophthalmic goiter, probably on account of some toxic action of the abnormal thyroid secretion on the heart muscle.

In the great majority of cases of auricular fibrillation we are dealing with a permanent condition, which persists in spite of all treatment. Even the paroxysmal form of the irregularity is remarkably difficult to control and we have no certain method of preventing or aborting the paroxysms. For example, in a case recently under observation at the University of Michigan Hospital, the frequent recurrence of the irregularity gave opportunity for testing the effect of many cardiac remedies. None proved very efficacious, though pilocarpin injections sometimes seemed to abort the attack.

Although the efforts to check auricular fibrillation have proved so futile, nevertheless it is in this class of disturbed rhythm that the most brilliant successes have been achieved with drugs of the digitalis group. These do not stop the fibrillation, but they slow the ventricles and render them less irregular. The pulse becomes larger and fuller, diuresis often sets in, the dyspnea lessens, and the swelling of the liver diminishes. In auricular fibrillation a large number of stimuli seem to originate in the auricles, and the ventricular rhythm depends on the number of these which succeed in crossing the bundle of His. Digitalis, by increasing the block at this point, reduces the number crossing and consequently the ventricular rate. Even such a partial regulation with a reduction of the ventricular rate to about 80 is highly advantageous, and may be followed by a most marked improvement in the circulation. When the ventricular rate is already much below 80, as happens occasionally, the value of digitalis is much less certain. Experience has shown that patients with auricular fibrillation and fast ventricular rate vary greatly in their reaction to digitalis medication, young individuals with mitral valve disease being far more favorably influenced than elderly patients with myocardial disease. According to Lewis[15] mitral disease is frequently associated with some damage to the His bundle. This reduces its conductivity, and the further reduction brought about by digitalis is responsible for the beneficial results of this drug in this class of patients. We should not forget, however, that young individuals, in general, are more apt to show a marked vagus control of the heart, and, that, in consequence of this, digitalis is probably more apt to produce vagus effects in young than in old patients.

CONCLUSIONS

Each form of irregularity has its own problems. With regard to treatment these have been in part solved, but for the most part they still await solution. To accomplish this we need more experimental evidence having direct bearing on the use of drugs in cardiac irregularities and we need, especially, studies concerning the effect of drugs on the irritability of the heart muscle, for abnormal irritability seems to play an important part in the causation of extrasystoles and auricular fibrillation. Finally, we need more accurate studies on the effect of cardiac remedies on patients with heart disease, following some such scheme as that recently suggested by Mackenzie.[16] From data thus obtained we may expect to be able to select drugs and to predict their effects with greater precision than has been possible in the past. Nor does it seem improbable that new drugs or new indications for old drugs will be discovered by such careful studies.

Production of Artificial Life.—The failure of scientists so far to produce "artificial life" is not to be charged against the science of biology. Very few of the attempts to produce "artificial life" have been made by biologists, who realize too well the complexity of the problems involved. The biologists will be satisfied for a number of years to come if they succeed merely in analyzing what goes on in a living cell, in terms of physical and chemical processes. From time to time they will attempt to imitate a structure or a process by means of a working model; but they will not speak of artificial life until they are quite sure of all the conditions that play a part in this most intricate of phenomena.—B. C. Gruenberg in *Scientific American.*

THE EFFECT OF THE DIGESTIVE SECRETIONS ON THE ACTIVITY OF DIGITALIS AND ALLIED DRUGS *

WORTH HALE
Assistant Pharmacologist, U. S. P. H. and M.-H. Service
WASHINGTON, D. C.

As is well known, the glucosids in general are comparatively unstable chemical substances and are easily broken down into a sugar and some other substance. A number of factors are operative in splitting up the glucosidal molecule, but chief among them, especially in the presence of heat, are certain enzymes, the alkalies, and the mineral acids.

In view of these facts it is not at all surprising to find that certain of the digitalis glucosids have been reported to be broken down to a greater or lesser degree, either by the enzymes of the gastric or pancreatic secretion, or by the acids or alkalies added to these enzymes to make them active. Three researches may be noted as specifically showing this deterioration.

In 1896 Deucher observed clinically in cases of heart disease and dropsical conditions that digitalin verum was almost invariably much more potent when given subcutaneously than when given by the mouth. As this difference was much greater than is common when other drugs are thus administered he came to the conclusion that the digitalin was probably changed either in the stomach or in the intestinal tract into partially inert compounds by the action of the hydrochloric acid of the stomach or by the ferments found in the stomach and intestine.

In an effort to prove whether this hypothesis was correct or not Deucher[1] carried out a series of experiments in which definite amounts of digitalin verum were subjected, with certain exceptions, for twenty-four hours to the action of artificial digestive secretions. For the purpose of subsequently determining the changes, if any, which were produced, frogs were injected with equivalent amounts of the digitalin, subjected to artificial digestion, and an undigested control, the time of appearance of the systolic stoppage of the exposed hearts being noted as an end reaction. From these experiments he came to the conclusion that the digitalin was partially broken up into inert compounds by the action chiefly of dilute hydrochloric acid, 0.2 per cent., although the presence of pepsin seemed to accelerate the breaking down to some extent. The pancreatic solution employed by him was found to be inactive.

Deucher further suggested the possibility that the other glucosids of the digitalis group might be broken up by the action of the digestive agents, but he seems to have only made experiments with digitalin verum.

In 1907 Löwy[2] supplemented Deucher's work by investigating the effect of acid, acid pepsin, and alkalies, on the infusion of digitalis, and on the pure principles helleborein and strophanthin. He found that in the presence of heat, after twenty-four hours, hydrochloric acid and acid pepsin solutions reduced the activity of the infusion and of helleborein. He concluded, however, that the 0.2 per cent. acid at the body temperature alone caused the deterioration noted and that the pepsin was without effect. Löwy also noted that moderately strong alkali solutions (0.5 per cent.) decreased the activity of the infusion.

The activity of strophanthin was not found to be changed by acid pepsin digestion.

As opposed to this latter view Hatcher,[3] in working with strophanthin, came to the conclusion that both acid peptic and alkaline pancreatic digestion for two hours caused some diminution in the toxicity of the strophanthin. In considering the opposed finding of the two investigators, however, it is to be noted that strophanthin is an indefinite term and it is quite possible that the two observers worked with different strophanthins, one of which was more easily attacked by the digestive agents.

As a fact of considerably more importance, it was found by Hatcher and Bailey[4] that the toxic dose of strophanthin for cats by the stomach was five or six times that by intravenous injection, and after a lengthy series of experiments they came to the conclusion that the lessened activity of the drug when given by the stomach depended only to a small degree on the destructive action of the digestive secretions, and that the chief factor in decreasing its toxicity depended on a delayed absorption.

Findings such as these with digitalin verum, with the infusion, and with strophanthin, raises the very important question of proper dosage of these bodies. With a drug so powerful as digitalis, no therapy can be regarded as safe unless the exact strength of the drug employed is known, and if deterioration goes on in the stomach and intestines before absorption these facts should be known.

To this end a number of further experiments along this line were deemed worth while, not only as confirmatory of the findings above recorded, but also to test the rate of deterioration by making use of an exact assay method for determining the degree of change of the substances in question, after subjecting them to the action of the digestive agents for a time more nearly analogous to the conditions found *in vivo*. These were accordingly tested to determine the degree of deterioration when subjected to the action of hydrochloric acid, with and without the addition of pepsin, and of alkali with pancreatin, and in certain instances of emulsin, a glucosidal-splitting ferment found in bitter almond and other seeds.

For the purpose of assaying the preparation before and after digestion the one-hour frog-heart method was used. This, in brief, consists in determining the least amount of the drug which will just produce permanent systole of the ventricle of the frog *Rana pipiens* at the end of one hour. The drug is injected in solution into the anterior lymph-sac, and a temperature of 22 C. is maintained throughout the experiment, the heart being exposed at the end of one hour.

DIGITOXIN

A control was first established for digitoxin by dissolving a weighed amount in 30 per cent. alcohol. The assay value by the method briefly described above was found to be 0.008 mg. per gram of frog weight.

To test the effect of the gastric secretion on digitoxin, a weighed amount placed in a cylinder was subjected to the action of an artificial gastric juice containing 0.25 per cent. hydrochloric acid and 0.1 per cent. scale pepsin. The undissolved digitoxin was placed in an incubator

THE EFFECT OF THE DIGESTIVE SECRETIONS ON THE ACTIVITY OF DIGITALIS AND ALLIED DRUGS *

WORTH HALE
Assistant Pharmacologist, U. S. P. H. and M.-H. Service
WASHINGTON, D. C.

As is well known, the glucosids in general are comparatively unstable chemical substances and are easily broken down into a sugar and some other substance. A number of factors are operative in splitting up the glucosidal molecule, but chief among them, especially in the presence of heat, are certain enzymes, the alkalies, and the mineral acids.

In view of these facts it is not at all surprising to find that certain of the digitalis glucosids have been reported to be broken down to a greater or lesser degree, either by the enzymes of the gastric or pancreatic secretion, or by the acids or alkalies added to these enzymes to make them active. Three researches may be noted as specifically showing this deterioration.

In 1896 Deucher observed clinically in cases of heart disease and dropsical conditions that digitalin verum was almost invariably much more potent when given subcutaneously than when given by the mouth. As this difference was much greater than is common when other drugs are thus administered he came to the conclusion that the digitalin was probably changed either in the stomach or in the intestinal tract into partially inert compounds by the action of the hydrochloric acid of the stomach or by the ferments found in the stomach and intestine.

In an effort to prove whether this hypothesis was correct or not Deucher[1] carried out a series of experiments in which definite amounts of digitalin verum were subjected, with certain exceptions, for twenty-four hours to the action of artificial digestive secretions. For the purpose of subsequently determining the changes, if any, which were produced, frogs were injected with equivalent amounts of the digitalin, subjected to artificial digestion, and an undigested control, the time of appearance of the systolic stoppage of the exposed hearts being noted as an end reaction. From these experiments he came to the conclusion that the digitalin was partially broken up into inert compounds by the action chiefly of dilute hydrochloric acid, 0.2 per cent., although the presence of pepsin seemed to accelerate the breaking down to some extent. The pancreatic solution employed by him was found to be inactive.

Deucher further suggested the possibility that the other glucosids of the digitalis group might be broken up by the action of the digestive agents, but he seems to have only made experiments with digitalin verum.

In 1907 Löwy[2] supplemented Deucher's work by investigating the effect of acid, acid pepsin, and alkalies, on the infusion of digitalis, and on the pure principles helleborein and strophanthin. He found that in the presence of heat, after twenty-four hours, hydrochloric acid and acid pepsin solutions reduced the activity of the infusion and of helleborein. He concluded, however, that the 0.2 per cent. acid at the body temperature alone caused the deterioration noted and that the pepsin was without effect. Löwy also noted that moderately strong alkali solutions (0.5 per cent.) decreased the activity of the infusion.

The activity of strophanthin was not found to be changed by acid pepsin digestion.

As opposed to this latter view Hatcher,[3] in working with strophanthin, came to the conclusion that both acid peptic and alkaline pancreatic digestion for two hours caused some diminution in the toxicity of the strophanthin. In considering the opposed finding of the two investigators, however, it is to be noted that strophanthin is an indefinite term and it is quite possible that the two observers worked with different strophanthins, one of which was more easily attacked by the digestive agents.

As a fact of considerably more importance, it was found by Hatcher and Bailey[4] that the toxic dose of strophanthin for cats by the stomach was five or six times that by intravenous injection, and after a lengthy series of experiments they came to the conclusion that the lessened activity of the drug when given by the stomach depended only to a small degree on the destructive action of the digestive secretions, and that the chief factor in decreasing its toxicity depended on a delayed absorption.

Findings such as these with digitalin verum, with the infusion, and with strophanthin, raises the very important question of proper dosage of these bodies. With a drug so powerful as digitalis, no therapy can be regarded as safe unless the exact strength of the drug employed is known, and if deterioration goes on in the stomach and intestines before absorption these facts should be known.

To this end a number of further experiments along this line were deemed worth while, not only as confirmatory of the findings above recorded, but also to test the rate of deterioration by making use of an exact assay method for determining the degree of change of the substances in question, after subjecting them to the action of the digestive agents for a time more nearly analogous to the conditions found *in vivo*. These were accordingly tested to determine the degree of deterioration when subjected to the action of hydrochloric acid, with and without the addition of pepsin, and of alkali with pancreatin, and in certain instances of emulsin, a glucosidal-splitting ferment found in bitter almond and other seeds.

For the purpose of assaying the preparation before and after digestion the one-hour frog-heart method was used. This, in brief, consists in determining the least amount of the drug which will just produce permanent systole of the ventricle of the frog *Rana pipiens* at the end of one hour. The drug is injected in solution into the anterior lymph-sac, and a temperature of 22 C. is maintained throughout the experiment, the heart being exposed at the end of one hour.

DIGITOXIN

A control was first established for digitoxin by dissolving a weighed amount in 30 per cent. alcohol. The assay value by the method briefly described above was found to be 0.008 mg. per gram of frog weight.

To test the effect of the gastric secretion on digitoxin, a weighed amount placed in a cylinder was subjected to the action of an artificial gastric juice containing 0.25 per cent. hydrochloric acid and 0.1 per cent. scale pepsin. The undissolved digitoxin was placed in an incubator at 38 for three hours, and was then taken up with enough alcohol to just form complete solution. This solution assayed 0.011 mg. per gram frog weight. A second weighed amount similarly treated assayed after three hours in the incubator, 0.010 mg. per gram frog weight. Eighteen hours later this solution of digitoxin which was kept at room temperature assayed 0.013 mg. per gram frog weight.

---

* Read in the Section on Pharmacology and Therapeutics of the American Medical Association, at the Sixty-Second Annual Session, held at Los Angeles, June, 1911.

[1] Deucher: Deutsch. Archiv. f. klin. Med., 1896, lvii, 1; 1896-7, lviii, 47.

[2] Löwy: Wien. klin. Wchnschr., 1906, xix, 1157.

[3] Hatcher: Am. Jour. Physiol., 1908, xxiii, 303.

[4] Hatcher, R. A., and Bailey, H. C.: Tincture of Strophanthus and Strophanthin, The Journal A. M. A., Jan. 2, 1909, p. 5.

A weighed amount of digitoxin was then subjected to the action of 0.25 per cent. hydrochloric acid for three hours at 38°. At the end of this time it assayed 0.01 mg. per gram frog weight; at the end of eighteen hours at room temperature it assayed 0.014 mg. This decrease in activity, approximately parallelling that of the acid pepsin digestion, would indicate that the acid alone was the active agent in breaking down the digitoxin molecule, and that the pepsin was inactive.

Pancreatic secretion containing the pancreatin 0.1 per cent. dissolved in 0.15 per cent. sodium carbonate was allowed to act at 38° on weighed amounts of digitoxin for periods of three hours, and also eighteen hours at room temperature. At the end of three hours the assay gave 0.008 mg. per gram frog weight in duplicate experiments, thus showing no decomposition from pancreatic digestion. When subjected to digestion for eighteen hours, however, there was some deterioration, the assay value being 0.010 mg.

FRENCH DIGITALIN

French digitalin, consisting mainly of digitalin verum, was tested, the undigested control assaying 0.012 mg. per gram of frog weight. A weighed amount was subjected to the action of an artificial gastric juice for a period of three hours. It then assayed 0.013 mg. per gram weight. After eighteen hours at room temperature the assay showed further deterioration, 0.016 mg. per gram frog weight being necessary to produce systolic stoppage of the heart. Hydrochloric acid alone was approximately equally effective in causing deterioration as the combined acid and pepsin.

No deterioration was obtained under treatment of weighed amounts of French digitalin with an artificial pancreatic secretion.

DIGITALEIN

Digitalein was assayed, the effective dose being 0.024 mg. per gram of frog weight.

In a weighed amount, 0.25 per cent. hydrochloric acid and 0.1 pepsin were added. After digestion at 38° for three hours the assay showed a deterioration, the amount then necessary to produce systolic stoppage of the heart being 0.032 mg. Hydrochloric acid, 0.25 per cent., without the pepsin caused deterioration so that at the end of three hours at 38°, 0.030 mg. was required to bring the ventricle into permanent systole.

Under artificial pancreatic digestion very little, or no deterioration, was observed. A value of 0.026 mg. was obtained, but owing to incomplete absorption in a large number of assays this result is to be questioned.

Digitalein was tested to determine the effect of emulsin, the glucosid-splitting ferment of bitter almond seeds. The assay value after three hours at 38° gave 0.028 mg. as the amount required to produce systole of the ventricle, thus showing a slight decomposition.

TINCTURE OF DIGITALIS

Having found by the above assays that the chief glucosids found in digitalis were less active after digestion with an artificial gastric juice, experiments were carried out with the tincture. As the glucosids digitoxin, digitalin, and digitalein, are all represented in the tincture, these experiments would also be expected to give analogous results and to be in the nature of duplicates.

The first tincture to be assayed gave a value before digestion of 0.010 c.c. per gram of frog weight. After evaporation of the alcohol, 0.25 per cent. hydrochloric acid and 0.1 per cent. pepsin were added and kept at 38° for three hours. At the end of that time the assay value was found to be 0.014 c.c.

A second tincture assayed 0.008 c.c. per gram of frog weight. An evaporated portion was subjected to artificial gastric digestion for three hours at 38°, and then gave an assay value of 0.012 c.c. After standing eighteen hours at room temperature the assay value was 0.016 c.c.

This tincture was subjected also to the action of an artificial pancreatic juice made up with 0.2 per cent. alkali and 0.1 per cent. pancreatin. In two experiments there was about 25 per cent. deterioration after three hours at 38°. Whether this is invariable cannot be stated, but in view of the fact that none of the glucosids showed deterioration, it may be questioned. It also brings up the point that in the crude tincture, enzymes natural to the digitalis leaf may become especially active with an alkali present, and thus explain the discrepancy in results. This point will be further investigated.

STROPHANTHIN

The discrepancy in the dose of strophanthin is so great by stomach and intravenously that, it was hoped in view of the deterioration with the digitalis glucosids, an investigation of the changes going on under artificial digestion might throw some further light on the question.

The control assay of strophanthin gave a value of 0.00055 mg. per gram of frog weight.

A weighed amount of strophanthin under artificial gastric digestion assayed 0.00065 mg.; thirty-six hours later the assay showed marked deterioration at room temperature, the value being 0.0015 mg. A second weighed sample after three hours' digestion assayed 0.0007 mg., and at the end of twenty-four hours at room temperature, 0.0010 mg. Pancreatic digestion showed much less action on strophanthin. A sample subjected to alkaline pancreatic juice for three hours assayed 0.0006 mg.; twenty-four hours later the assay was still 0.0006 mg. A second sample under pancreatic digestion for three hours showed no deterioration, nor when tested after twenty-four and thirty-six hours at room temperature.

Emulsin had a very slight effect, reducing the activity after three hours in the incubator, to 0.0007 mg. per gram frog weight.

That strophanthin might also be destroyed in the liver is a possible conclusion, but experiments with minced cats' and frogs' livers showed that no decomposition took place after two hours at 38°.

From this series of experiments it is to be noted that the acid of the gastric secretion invariably causes some diminution in the action of the glucosids of digitalis and strophanthus. It is not believed, however, that an exact determination of the degree of decomposition in practice can be made, for in all probability the rate is somewhat more rapid under actual conditions, owing to the motility of the stomach and the comparatively greater dilution of the glucosids. The rate of deterioration, however, appears to be about the same for the various glucosids, about 25 to 35 per cent. in three hours, so that this fact need not be taken into notice in therapeutics. The further factor, however, of the action of the decomposition products of these glucosids must be considered, and it is possible that certain of the untoward effects of digitalis medication may be due to them. At any rate in so far as is possible it would seem advisable to prevent such decomposition, and it is suggested that this might be done by requiring the official galenical preparations to be neutral, and in practice, by prescribing an alkali along with digitalis. Ignoring the specific irritant action of these bodies on the intestinal tract also, it would seem advisable that the drug should be given between, rather than at meals, when the gastric acidity is at the maximum and such a procedure might possibly not cause undue irritation if a large quantity of fluid were taken at the same time.

SOME FACTORS IN THE TREATMENT OF MYOCARDIAL LESIONS *

WILLIAM WATT KERR, M.D.
Professor of Clinical Medicine, University of California,
SAN FRANCISCO

The difficulty of arriving at a positive conclusion as to the exact nature of the tissue changes existing in the cardiac muscle of patients presenting undoubted evidences of heart disease makes it prudent to discuss the following cases under a clinical title rather than one based on morbid anatomy, for few, if any, can distinguish between the signs of chronic myocarditis and those of degeneration, or can say when the molecular disturbance consequent on febrile or other intoxication ends and the congestion with small-cell infiltration of a myocarditis begins. It is true that the physician draws his own mental picture of the changes in each case, but he will have difficulty in describing it in words that will stand the criticism of his audience.

The teachings of Dr. James MacKenzie and other members of the English school have done much to increase our knowledge regarding diseases of the heart, and have given additional impetus to original research in this particular branch of medicine, but, up to the present time, this advance does not appear to be accompanied by any corresponding progress in methods of treatment. It may be an erroneous impression on my part, but it would appear as if the tendency were to give exclusive attention to remedies which influence the mechanism of the heart and to neglect or to discuss superfically treatment that might alleviate or arrest changes in the cardiac muscle itself. Only too often do cases present themselves in which all treatment seems to have ceased after a successful or unsuccessful effort has been made to whip a heart into compensation by means of some member of the digitalis group, and although in many instances this is the result of the patient ceasing to present himself for advice just so soon as he feels well enough to attend to his daily vocation, nevertheless this would be very greatly modified if from the commencement the patient were made to understand that after his apparent recovery it would be necessary for him to follow certain rules of life or to continue some particular line of medication if he wished to retain his restored health.

My object in considering "some factors in the treatment of myocardial lesions" is to emphasize the benefits that very often accrue from the systematic and persistent use of these remedies, generally described as alteratives, which in some direct, but imperfectly understood manner, influence the nutrition of the myocardium. I have no new agents to suggest; all of them are familiar to every practitioner, but in the majority of books they are mentioned so cursorily in comparison with the prolonged discussions on digitalis, strophanthus and squills that very often their value is underestimated, no fair trial is given them and consequently many cases that would have been benefited by their early and persistent administration are allowed to go along unchecked until the patient becomes a chronic sufferer, to whom death comes as a merciful relief.

When we are brought in contact with a weak myocardium the first endeavor is clearly to depict the case, to decide whether the condition is associated with a valvular lesion, as in combined endocarditis and myocarditis, or if it is secondary to a valvular lesion, as in failed compensation; to satisfy ourselves whether it is due to lack of nutrition, as in aortic and coronary disease and anemia, or is the result of toxins such as we find in influenza, syphilis, uterine fibroids, habitual constipation or disordered metabolism. Is it not possible that, while it is fully realized how much all the organs of the body depend on cardiac efficiency for their functional activity, it is not so constantly borne in mind that disturbance in any part of the body may have a deleterious influence on the heart? I mention this because much of the recent literature on disease of the circulatory system conveys the impression that individual study of diseases of the heart is liable to lead to the same results as specialization in the study of other organs; it narrows the clinical horizon; and while this may not be fraught with much danger to the man who is treating only the organs of special sense, it is absolutely inadmissible to the internist who is dealing with viscera which are so mutually dependent on one another for the normal performance of their functions.

One of the first criticisms that might be made regarding the use of such constitutional remedies as the iodids in the treatment of myocardial disorders is the fact that very frequently their administration is not continued for a sufficient length of time to obtain results. In cases of syphilis the physician does not hesitate to keep his patient taking these remedies for weeks, or, it may be, months, without any interruption; but in the treatment of myocardial inefficiency he very frequently stops after ten days or two weeks because he has not obtained the same brilliant results that so often follow the use of digitalis for the same length of time; he seems to argue that because digitalis often restores compensation in a case of valvular disease within two weeks, therefore, the iodids, if they are going to be of any service, must in the same length of time restore to full activity muscular fibers which have been poisoned and in which the toxic process is still going on; he seems to forget that he is not dealing with a cardiac stimulant, but that some form of malnutrition or imperfect elimination has to be corrected before the muscle can recover so as fully to respond to stimulation, and it is this correction that the iodids accomplish.

The following case was one that impressed me very much with the benefits that may sometimes arise from the prolonged use of iodids:

Case 1.—Mr. A. W. consulted me in August, 1904. For some weeks he had suffered from dyspnea on exertion and hardly a night passed without an attack of cardiac asthma, so that latterly he dreaded going to bed and always slept in an armchair. He was of spare build, had led a good life,

---

* Read in the Section on Pharmacology and Therapeutics of the American Medical Association, at the Sixty-Second Annual Session, held at Los Angeles, June, 1911.

smoked not more than five cigars daily, and denied all luetic history. Examination showed the blood-vessels moderately thickened, the area of cardiac dulness normal, sounds weak but otherwise normal, the liver tender and the area of hepatic dulness increased. All other organs were normal. The patient's physician told me that he had already given him, at different times, digitalis, strychnin and nitroglycerin, but without any more than evanescent relief and that the conditions were growing worse. Now he was given proto-iodid of mercury for ten days and then a reliable preparation of digitalis with the idea that the state of the liver had probably prevented its beneficial effects on the former occasion. The patient experienced considerable relief so that he could spend his nights in bed, but his rest was very much disturbed and he was far from well.

About the end of September I discontinued the digitalis, ordered 10 gr. of potassium iodid three times daily, told the patient to continue this for two weeks and then report his progress. On October 3 an accident occurred that completely incapacitated me for work during the next four months, but at the end of that time the patient came to my office, saying that he did not wish to consult me about himself as he was better than he had been for years and his friends remarked on his improved appearance; he only desired to congratulate me on my escape and make sure that I was alive, as he might want me again. In response to an inquiry about his own condition he said that after taking the last medicine, which was the iodid, he came to report according to his instructions but could not see me on account of my sickness; he therefore on his own responsibility continued taking the iodod and was still taking it at that time, from the middle of September, 1904, to February, 1905, and, he added, "Doctor, I never felt better than I do now and I am afraid to stop it." He is now 73 years of age, attends to business regularly and has occasional attacks of cardiac weakness, generally following a cold or some other slight indisposition, but never approaching his former seizures in severity.

Case 2.—Mr. K., aged 58, first consulted me Sept. 7, 1906. He complained of a sensation of oppression over the sternum and pain in the left forearm induced by the least exertion. He had suffered more or less since an attack of influenza five years previously but had been very sick since April 18, 1906, so that he could not walk one block without making some pretext that would enable him to stand still for a few moments. The cardiac apex was in the fifth space, half an inch beyond the nipple line, the mitral sound was impure, a systolic murmur could be heard over the aorta with a spluttering second sound, the blood-vessels were thickened, and an arcus senilis was well marked; the liver was large, distinctly palpable but very slightly tender. There was no luetic history. Already the patient had received nitroglycerin, digitalis and caffein without benefit. At once 10 gr. of potassium iodid three times daily were ordered for him, and every other night he received a pill containing blue mass and rhubarb compound. At the end of five days he said that the pain and oppression were very much less both in frequency and severity, also that he could walk for some distance with ease, and as he lived over one hundred miles from San Francisco and business affairs demanded his presence, he decided to return home and come to San Francisco every few days, making a round trip of over two hundred miles to report his condition. Twelve days later he was very much better, had been absolutely free from pain during the previous week, although he had walked as many as ten blocks without resting, the area of heart dulness had become normal, the sounds were much clearer, and the liver was also improved. October 1 he complained of feeling very much depressed and as he had been taking potash continually for more than three weeks I thought that possibly it might be responsible for those feelings and consequently substituted the proto-iodid of mercury for it, but at the end of ten days he felt just as poorly, and a mixture containing arsenic and nitroglycerin was prescribed. This also failed and he was put back on potassium iodid with such happy results that late in November he started on a pleasure trip through British Columbia and Alaska. He continued taking his iodid all this time and did not discontinue it until the end of April, 1907. He gained 20 pounds in weight.

I did not hear from him again until Sept. 23, 1907, when he came to me from some "springs," where he had been spending a short holiday with friends, who advised him to take a hot mineral bath for the purpose of breaking up a cold; but while in the bath he experienced a sudden onset of severe cardiac oppression which still continued in a milder degree and from which he never fully recovered, although examination did not reveal any change. Under treatment with cardiac stimulants, vasodilators and iodids given at different times he improved so that during the remaining two and a half years of his life he was able to attend to his business and make at least two trips from California to New York and other cities, but he never got back to the buoyant condition of health he enjoyed before taking the hot mineral bath. The last time that I heard from him was late in 1909, when he was having repeated attacks of cardiac asthma, and early in 1910 I was notified that he had died at his own home in the country, but that an autopsy could not be obtained.

Not only must the prolonged administration of these remedies be insisted on, but the dosage has to be taken into consideration in some patients on account of their idiosyncrasy regarding iodids.

Case 3.—The patient, Mr. C., was a man aged 47, with grey hair, weighing 257 pounds. Exertion produced angina pain in the chest and right arm, which was most severe in the right wrist; heart area was increased nearly 1 inch to the left of the nipple line. There were no cardiac murmurs but the aortic sound was accentuated and impure; the liver was large and tender, and there were tender nodes at the level of the fifth and seventh dorsal vertebræ to the right of the spinal column. The patient had been sick for four months before I saw him on Sept. 16, 1907. His diet was restricted and consecutively he received proto-iodid of mercury, arsenic and nitroglycerin, all of which afforded him some, but not very much, relief. November 6 he was given his first dose of iodid which very soon produced iodism and the remedy was discontinued for a few days and then given in a saturated solution with the instructions that he should begin with small doses and gradually increase the amount; but various trials showed his inability to take more than four drops of the saturated solution twice daily without producing coryza and pain in his jaws. This seemed such a useless dose that my inclination was to abandon the use of the drug, but the patient asked permission to continue it, as he felt much better during its administration. In April, 1908, he left San Francisco and returned in the following July when he told me that during his absence he had been a member of a prospecting party, working at an elevation of 4,500 feet, and that he had been able to do chores around the camp and carry buckets of water along the trails without suffering any inconvenience. I saw him last in the end of 1909, when he told me that he had always kept his iodid "on tap" and took it in the same small doses for a few weeks at a time whenever he felt that he was losing ground. I mention this case simply to illustrate the fact that good results may be obtained from the protracted use of small doses when the patient shows an idiosyncrasy regarding the drug, my previous opinion having been that even under such conditions small doses were useless.

In children similar good results follow the prolonged administration of the syrup of the iodid of iron. Among other cases there are two boys, members of different families, who have been under my observation for the last three years with weak heart muscles, so that every few months their hearts would dilate, murmurs of muscular incompetence would develop at the mitral orifice, the patients would be put to bed and kept on different preparations of iron, arsenic and digitalis until compensation was restored, and then after a time history would repeat itself. Since they were given the iodid of iron their condition has improved immensely, in regard both to their hearts and to their general health.

A sufficient number of cases have been mentioned to illustrate the point for which I am contending, but it might be well to mention some features that were common to all of them. They all showed evidences of weak myocardium and hepatic enlargement without signs of local edema or general dropsy; the question of acquired or inherited syphilis was thoroughly exploited with uniformly negative results; improvement took place in the older patients with diseased blood-vessels as well as in the boys whose arteries were healthy; all of them gained weight during the treatment. These facts suggest the thought that the cardiac disturbance was part of a constitutional disorder, and that there was just as little chance of relieving the patients by treatment directed to the heart alone as there would be of curing a diabetic eczema by means of no other agency than a local application.

It is impossible to do more than theorize regarding the *modus operandi* of the iodids because our knowledge of alteratives, the physiology of the lymphatic system and the relation of both to general metabolic processes is still very scanty. It may be that where there is some disturbance of metabolism, resulting either from the introduction of toxins into the body or some other cause, secondary injurious products are formed in amounts which the liver and other glands are incapable of destroying or eliminating, and that the iodids promote their elimination in a manner similar to that in which they eliminate the products of the syphilitic poison. What toxins cause the trouble in these cases it is impossible to say, because, just as specific toxins manifest their affinity for different tissues, it is only natural to conclude that the resulting or secondary toxins will exhibit a corresponding variation; but some recent work in metabolism prompts the suggestion that accumulation of lactic acid in the tissues, either as the result of its excessive production or defective destruction and elimination, is responsible for a considerable proportion of the cases of myocardial distress. The following are the premises on which the hypothesis is based.

TOXIC EFFECT OF LACTIC ACID ON THE HEART

Martin Flack[1] states that "if a frog's ventricle is placed in a weak solution of lactic acid (1 in 10,000 normal saline solution) the contractions become less and less, so that finally the ventricle stops in a state of complete relaxation"; and Bachmann[2] perfused rabbits' hearts with solutions of lactic acid and obtained increased rate with greatly diminished force of contraction and a simultaneous dilatation of the coronary arteries, a fact that would indicate lactic acid to be a paralyzing agent for all muscles of the cardiovascular system; neither did it require a strong solution; but even amounts so small as those occasionally found in the blood of a normal rabbit had some paralyzing effect.

THE SOURCE OF LACTIC ACID IN THE HUMAN BODY

Lactic acid is produced in the human body in the process of metabolism and also as a result of muscular exertion. Ryffel[3] demonstrates conclusively that lactic acid is formed from glucose as well as from other carbohydrates and possibly to a lesser extent from proteids, and quotes Magnus Levy's suggestion that lactic acid may be an intermediate stage in the transformation of carbohydrate to the higher fatty acids, which is known to take place in the body in the formation of fat from carbohydrate. He also mentions the observations of different investigators which tend to show that increased consumption of glucose in muscles is accompanied by a corresponding increase in the formation of lactic acids. This last fact is of interest in relation to the production of lactic acid in muscular tissues as a result of their activity, and especially in connection with the particular organ now under consideration, because, while most observations have been made on the muscles of animals, Prof. Hugh A. Stewart[4] has shown that dextrose is consumed in the human heart. Two and a half hours after the death of a patient he excised the heart and perfused it with a solution of dextrose, with the result that in ten minutes the whole heart was beating strongly; it continued to beat until the perfusion was stopped, more than two hours later, and the washings tested for the amount of dextrose. The analysis showed that the human heart, like that of other animals, is capable of breaking down the dextrose of the perfusing fluid. Locke and Rosenheim,[5] working on the rabbit's isolated heart, had previously shown that the consumption of dextrose depended on some definite relation between the potassium and calcium salts in the perfusing fluid, and concluded that the calcium salt is especially necessary for the conversion of chemical changes into mechanical work.

THE NORMAL FATE OF LACTIC ACID IN THE HUMAN BODY

As lactic acid is a cardiovascular poison normally produced within the body, it is important that we should know how it is destroyed before it is present in such quantity as to produce its toxic effects. Normally the great bulk of lactic acid is destroyed in the tissues by various processes. Embden and Salomon have shown that some of it may be retransformed into glucose by a process of condensation, and, as we have already seen, some of it may become fat. Furthermore, Stoklasa obtained from muscle and blood two anaerobic ferments, one which converted glucose into lactic acid and another which changed the lactic acid into alcohol and carbon dioxid. Lastly, experimentally it was demonstrated that excised "muscle kept in air or nitrogen showed a gradual increase of lactic acid, the rate of which depended on the temperature, until finally irritability was lost, when there was no further increase of lactic acid. If, however, the muscle was kept in oxygen there was practically no such increase at physiologic temperatures, and the loss of irritability was indefinitely postponed." From these and similar observations it was concluded that an adequate supply of oxygen not only prevents the accumulation of lactic acid, but even enables the muscle to destroy preformed lactic acid. This may be due to a direct oxidation of the acid, or it may be the result of the action of the oxygen on the alcohol, which we saw was one of the products of anaerobic fermentation, so that by removal of this product further anaerobic decomposition of the lactic acid is facilitated.

Ryffel settled the question regarding the relation between muscular exertion and the formation of lactic acid in the human subject by observing:

> The lactic acid in urine from competitors in a twenty-four-hour track-walking race was in no case above 6.5 mg. per hour, but found relatively large quantities in that passed after violent exercise—430 mg. after 0.36 mile, 818 mg. after 0.6 mile, running as fast as possible around a track 33 laps to the mile. The lactic acid in the blood, taken from a vein in the forearm immediately after the exercise, was also increased

in one case from 12.5 mg. at rest to 70.8 mg. per 100 c.c. Excess of lactic acid disappeared from the urine in about thirty minutes after stopping, but in forty-five minutes the lactic acid of the blood was not quite reduced to normal (15.9 mg. per 100 c.c.).

He concludes that the important factor in the accumulation of lactic acid from muscular work "is the relation between the activity of the muscles and their supply of oxygen."

At rest the muscles are fully supplied with oxygen by the circulation. This is also practically the case with limited activity, but, when the activity is great, the oxygen supply, although increased, is not sufficient to prevent the formation of excess of lactic acid, which makes its way into the blood, and, if in sufficient concentration, is excreted by the kidneys. Lactic acid, moreover, is quickly oxidized by the tissues, so that the return to the normal at rest is fairly rapid, occupying less than one hour after short periods of violent activity.

The importance of this work in relation to myocardial disorders is more fully recognized when we notice the different conditions that may lead to accumulation of lactic acid in the tissues; these are: (1) Increased and *rapid* formation of lactic acid by violent muscular activity; (2) inadequate supply of oxygen to the tissues; (3) absence or diminution of the lactic acid destroying ferment in the tissues; (4) absorption of lactic acid from the alimentary canal; (5) excessive supply of carbohydrate food. Possibly the last three are all closely related because there is experimental evidence to show that lactic acid is both formed and destroyed in the liver, just as in the muscles of the body. We also saw that it might accumulate in the tissues if there were not enough oxygen supplied to facilitate its destruction, and so, in like manner, since the transformation of carbohydrates is a function of the liver cell, it is easy to conceive that as the result of either excessive carbohydrate supply or diminished hepatic activity lactic acid may accumulate during the process of transforming carbohydrates to fat.

The summary of these different observations that I have presented is that, so far as they relate to the heart, the muscles of the whole cardiovascular system are poisoned by a very slight increase in the amount of lactic acid in the tissues; that this excess may be produced by perfectly physiologic processes, such as violent exertion, and when respiration in the same length of time cannot supply an equivalent increase of oxygen for the destruction of the acid, accumulation takes place. Or the excess and accumulation may be due to defective metabolism arising from a variety of causes already mentioned.

These observations show that the myocardial changes found in people who have been subjected to hard muscular exertion, are not necessarily secondary to those found in the coronary circulation, but that both may be due to a common toxin; they indicate where we may look for the cause of the disturbance when treating cases such as those mentioned in an earlier part of this paper; and, lastly, they give us the opportunity of adopting a line of treatment, both medicinal and dietetic, which promises better results than that now generally followed.

I do not wish to be understood as asserting that lactic acid is the only or most active product of metabolism in producing cardiovascular disturbance; my only object was to call attention to the great work that is being done by the physiologic and pathologic chemists to aid us in the treatment of the diseases now under consideration; at present the whole subject, so far as its application to the treatment of heart disease is concerned, is in the embryonic stage, but to me it carries much promise for the future. Everyone engaged in the practice of our profession must at one time or another have felt how eminently unsatisfactory are our present methods of treatment, how, in the majority of cases, our most brilliant results are only temporary improvements and short postponements of the inevitable day, and, as the patient leaves the consulting room, there remains behind him the feeling that we have never really reached a basis on which reasonable hopes for a cure may be established. With a growing knowledge of the chemistry of normal and abnormal metabolism it is probable that much of this will be changed, and that, especially among our younger patients, much will be done to restore a debilitated heart to its full vigor and also to prevent many of the cardio-vascular changes consequent on infections and malnutrition.

Another matter of interest is the use of the calcium salts in the treatment of myocardial weakness during prolonged or severe pyrexia, such as we find in pneumonia or the continued fevers. Early in 1908, Sir Lauder Brunton advised the use of calcium chlorid, in doses of from five to ten grains every four hours, for the purpose of maintaining the heart's action when failure was imminent in an elderly woman who was suffering from an influenza pneumonia. He based the advice on his knowledge that calcium chlorid is a constituent of Ringer's solution, which is used for perfusing isolated hearts during physiologic experiments. Many years ago Dr. Ringer observed that when the frog's heart was perfused with a sodium chlorid solution in distilled water the heart's action was not sustained so long as when the solution was made with water drawn from the ordinary faucet, and on examination found that the latter contains calcium salts, which, of course, were removed during the process of distillation, and since that time it has been generally recognized that the sodium chlorid solution will stimulate the heart to activity, but that the addition of calcium is absolutely necessary if it be desired to continue the contractions for any length of time.

Since that time Locke and Rosenheim, as has already been mentioned, have given the explanation of the phenomenon by showing that in the perfused heart "the consumption of dextrose is dependent on a certain concentration and balance of the calcium and potassium in the perfusion fluid, and they conclude that these salts, more especially calcium, are necessary for the conversion of the chemical changes into mechanical work." During the last three years I have followed Sir Lauder Brunton's suggestions in the treatment of pneumonia and also typhoid fever and have been most favorably impressed with the results, possibly from the fact that the administration of the calcium was commenced early in the course of the disease and continued until the beginning of convalescence with the hope of maintaining the heart's action rather than of reestablishing it when failure had commenced.

I must offer an apology for submitting a line of treatment that at the present time is so problematical. It is true that, like the blind man whose sight was subsequently fully restored, we now see things dimly, "men as trees walking"; but possibly the day is not far distant when we shall have a broader and a fuller vision. At any rate, the object of this paper will be served if it directs the attention of physicians, situated similarly to myself, to the work that is being done in behalf of treatment by those who devote themselves to the elucidation of problems in metabolism; and it may be that the latter gentlemen will be stimulated to further endeavor by the knowledge that their work is appreciated and waited for by the clinician, as well as by the thought that, in the words of Robert Burns, "A chiel's amang you takin' notes, and faith he'll prent 'em."

2605 California Street.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. SCHMOLL, KERR, HEWLETT AND HALE

Dr. William B. Snow, New York: It seems to me that in the study of cardiovascular derangements it is of first importance to consider the causes and their correction. It cannot be doubted by the clinician that the origin of these troubles is largely toxic. That the conditions originate in the alimentary canal through overfeeding, errors of digestion and an imperfect metabolism—particularly the first—seems to have been demonstrated. In my judgment the study of heart lesions should be along the same lines as the study of so-called rheumatic conditions, recognizing as causes the toxic effects of overfeeding, poor digestion and impaired metabolism. The regulation of diet to the demands of exercise and maintenance of body weight is, therefore, of first importance in their management. Each case is a clinical study in itself: the symptom-complex presenting is rarely the same in all particulars in any two cases. The treatment cannot be limited to the employment of drugs. Dietetic regulation and the employment of physical agents which tend to restore normal functions are always indicated. In my experience I have found no agent so effective in eliminating the various conditions of toxemia as the radiant light bath, or prolonged application of radiant light to the body with the incandescent lamps of high candle-power. The effect of radiant light on metabolism is remarkable in bringing about normal metabolism. As hypertension is more often the cause of arterial degeneration than any other and as hypertension is caused by toxemia, the indications are two: the relief of hypertension and the relief of the cause of hypertension—d'Arsonvalization for the former, and the regulation of the diet with the institution of habits of exercise for the other.

Dr. Boardman Reed, Alhambra, Cal.: I feel that the importance of a thorough study of the drugs we have been having cannot be overrated and yet my experience is that, as practical clinicians, we need to know more about the effect of diet and exercise and baths and all that sort of thing. That is, we can do a good deal more with these hygienic and physical measures than we can with drugs. We cannot know too much about drugs, but we need to know and use more the other line of treatment, according to my own experience. I do not think we realize enough the importance of diet. I fully agree with Dr. Snow in regard to what he said about overeating. I am sure that overeating and overdrinking cause more arteriosclerosis and cardiac affections than any other cause, among Americans, at least. I suppose that among the working-class, syphilis and muscular strain produce as much, but among the middle-class Americans overeating is a chief cause of vascular trouble, and I feel that we cannot emphasize that fact and apply the knowledge too much in our practice.

Dr. Ray Lyman Wilbur, San Francisco: I consider the points that Dr. Schmoll makes in regard to functional testing of the heart, aside from physical findings, well taken. I have seen a number of cases of young girls who had been kept in bed because they apparently had enlarged hearts and cardiac murmurs. They often had deviation in the shape of the thorax and in the position of the diaphragm, and I think they belong to the class of transient murmurs so common in young girls. Friedreich Müller says 30 per cent. of young girls present cardiac murmurs, unassociated with disease processes, and the physician is apt, when finding such a murmur, if nervousness is associated with it, to imagine that the child is in a much worse condition than it really is. I have watched some such patients for a number of years and the cases have all cleared up when there was no previous history of rheumatism. From the standpoint of practical treatment I have had more satisfaction from potassium iodid, as recommended by Dr. Kerr, than from almost anything else administered in various heart conditions, particularly in patients with attacks of acute dyspnea without edema, usually neurotic individuals without a syphilitic history. Whether the administration of potassium iodid has an effect on the thyroid, because of which we get some effect on the heart, I do not know, but I do know that clinically I have found it of great value in the class of cases which Dr. Kerr describes.

THE TREATMENT OF GASTRIC ULCER

WILLIAM J. MALLORY, M.D.
Instructor in Medicine in the George Washington University and
Attending Physician to the Out-Patient Department of the University Hospital
WASHINGTON, D. C.

The chief indication in all cases of gastric ulcer is rest and protection of the affected part, but here one is brought face to face with an opposite indication in the necessity of nourishing a patient who has already been brought low by a reduced diet, poor digestion, and hemorrhage.

Which of these indications should receive the greatest consideration must depend on the condition of the individual patient. Herein lies the explanation for a certain number of failures which occur when one follows one of the accepted plans of treatment as outlined by rules and tables. One must be governed by principles rather than rules, and in every instance the patient, as well as the case, must be considered.

When there has been recent hemorrhage the patient should be kept absolutely quiet in bed, not even rising to empty the bowels or bladder. Food by mouth should be reduced to a minimum or absolutely forbidden, according to the severity of the case. Under these circumstances an attempt should be made to nourish the patient by enemas and this method should be followed as long as tolerated. But one should not be misled with regard to the amount of nourishment the patient is receiving. Practically, it is not possible to maintain the patient's nutrition by enemas alone but they are of help in the early stage. The following are examples of some of the nutrient enemas which have been found satisfactory:

	Gm.	Calories
V. Leube—		
Finely scraped meat	50 (1⅔ oz.)	40
Raw pancreas, chopped	50 (1⅔ oz.)	85
Rubbed up with enough water to make	250 (8⅔ oz.)	..
		125
Forscheimer—		
Peptonized milk	200 (7 oz.)	80
Eggs	2	150
Brandy	30 (1 oz.)	100
		330
Eggs	3	225
Milk	300 (10 oz.)	195
Common salt	3 (45 grains)	...
		420
Boas—		
Yolks of two eggs		116
Milk	250 (8⅔ oz.)	160
		276

A method of feeding introduced by Einhorn[1] and termed duodenal alimentation should be mentioned. He uses a long, small, soft rubber tube, having a small metallic capsule at one end. This is passed into the stomach and allowed to remain until the capsule passes into the duodenum. The other end is made fast by means of adhesive plaster or string, and liquid food is introduced directly into the duodenum. The tube is allowed to remain in position for from ten to fourteen days. In Einhorn's hands, this enabled him to feed and maintain the weight of patients who could not otherwise retain food.

---

[1] Einhorn: Med. Rec., 1910, lxxviii, 92.

All of the diet-lists given have the common feature of beginning with a minimum quantity of soft or liquid food, gradually increasing over a period of from two to four weeks till the normal quantity is again reached. They all have the disadvantage of being tables; that is, it is naturally suggested that there is some advantage in the particular proportions in which the various substances are given, rather than in the principle on which they are based. Diet-lists are given in every text-book dealing with this subject and need not be repeated here.

The more recent Lenhartz diet is based on the physiologic fact that the stomach, even when empty, is not at rest. Lenhartz thinks it is therefore unnecessary to forbid all food by mouth; on the contrary, since the body has suffered a loss of its protein, the cell-building material, both through insufficient supply and through hemorrhage, it is highly necessary to replace this, and he finds eggs especially suited for this purpose. In addition, egg albumin has the power of combining with a maximum quantity of hydrochloric acid, thus protecting the damaged mucosa from digestion. He objects to the Laube and Penzoldt diets on account of the excessive quantity of fluid they contain.

There has been a warm discussion over the respective merits of the different diets. Some reliable observers report, after the use of the Lenhartz diet, a prompt relief of pain, fewer recurrences of hemorrhages, a gain in weight, and a shorter period of confinement to bed. Others report unfavorable results, no less an authority than Ewald[2] expressing decided disapproval.

If there is no agreement as to details, however, there are certain basic principles so obvious that all acknowledge their importance, and these principles, rather than arbitrary rules, should govern us in selecting a diet, for, after all, unless the diet is adjusted to suit the case rather than the disease, the treatment will be unsatisfactory. All food should be given in a finely divided form, in order to avoid unnecessary mechanical action and possible injury to the ulcerated surface.

Its chemical composition should be such that it does not offer an excessive physiologic stimulus; that is, it should tend to reduce the acidity rather than to increase it. Over this one point there has been much discussion, some arguing in favor of a rich protein diet on the ground that it will neutralize the largest amount of hydrochloric acid, others against protein diet because it is a natural stimulus to the secretion of hydrochloric acid. In fact, it is of more importance in what form the food is given and what particular variety of protein is used. Except when given cold for the purpose of counteracting nausea, the food should be just a degree or two warmer than the body.

It should be of high caloric value; that is, it should be as nutritious as possible, but not bulky, and in order to avoid distention it should be given in small quantities, frequently repeated. Little salt should be used in the preparation of the food or at table, because it acts in two ways to increase the secretion of hydrochloric acid, first, as a condiment and second, by contributing one of the principal elements for its formation.[3]

In the light of these obvious requirements of the damaged stomach, consider for a moment the well-known diets. Leube uses, in the first and second ten-day period, meat broth and bouillon; in the third period, scraped raw ham and half-raw beefsteak, and in the fourth, red roast beef.

Penzoldt used meat broth and bouillon in the first, second and third ten-day periods, and in the third, raw beef-sausage was allowed. Bouillon was allowed in the fourth period. Lenhartz allows raw chopped meat after the sixth day, and raw ham after the tenth day.

Now, it is a well-recognized fact of physiology that meat extract acting through the pyloric glands is a natural physiologic stimulus to the secretion of hydrochloric acid.[4] Raw meat not only contains more extractives but is less easily digested than cooked meat,[5] and has no advantage unless we desire to increase the secretions of the stomach, which is not the case in gastric ulcer. The nutrient value of the meat extract varies greatly, but it is given by Strauss as from 4 to 12 calories per 100 c.c.; while 100 c.c. of milk containing 3⅓ per cent. of cream has 65 calories; the same quantity containing 10 per cent. of cream has 124 calories.

From these facts it is certainly clear that raw meat, especially cured meat such as scraped ham, as well as bouillon, meat broth and rich meat soups, are unsuitable ingredients for diet in cases of gastric ulcer, for here a diet is needed which is easily digested, leaves the stomach promptly, and does not tend to increase the hydrochloric acid.

In this connection it should be remembered that milk, cream, unsalted butter, and olive oil should be used to as great an extent as possible, on account of their higher nutrient value, liquid form and, last but not least, because the fats tend to reduce the acidity. They leave the stomach promptly and tend to reduce the pyloric spasm which is often present when the ulcer is situated in that region.

Therefore, when the feeding by mouth is resumed, the diet should consist of milk with from 3 to 10 per cent. of cream, thoroughly cooked porridge and oatmeal, rice-meal, corn-meal, with milk, cream and sugar added to taste. Raw or very soft boiled eggs, crackers, buttered toast or milk toast to be added later. Puree of peas, potatoes and poached eggs, junket flavored with fruit juices and custards are also suitable.

Malted milk and the various concentrated prepared foods can be added to give variety to the diet. Pea-soup, sago, tapioca, minced chicken, tender fresh fish, brains and sweetbreads should be added later. The quantity taken at one meal should never exceed 250 gm., or 8 ounces. The temperature should not be above 38 or 39 C. (101-102 F.); that is, warm but not hot.

The medical treatment is directed to reducing the acidity, relieving pain and pylorospasm, and possibly toward exerting some direct influence on the ulcer itself. As constipation is usually present, it must be taken into consideration and the treatment modified accordingly.

The alkalies certainly reduce the acidity by combining with the excess of hydrochloric acid. They should therefore be given in large doses about an hour after meals, and repeated if necessary whenever pain occurs. The following prescriptions are used and recommended by men of wide experience:

[3] Cohnheim, O.: Die Physiologie des Verdauung und Ernährung, Berlin, 1908, p. 345.

[4] Cohnheim, O.: Die Physiologie des Verdauung und Ernährung, Berlin, 1908, p. 54.

[5] Schmidt, Adolf: Diagnose und Therapie chronischer Diarrhoen, Samml. Zwangl. Abhandlungen a. d. Geb. d. Verdauungs u. Stoffechs-Kr., ii, No. 1, p. 29.

Matthes of Cologne:

℞	Gm. or c.c.		
Infusi radicis rhei	150		℥ v
Sodii bicarbonatis	6		ʒ jss
Olei menthæ piperitæ	3		♏ xlv

Misce S. A teaspoonful twice daily.

Ewald:

℞	Gm. or c.c.		
Magnesiæ ustæ (magnesii oxidi)			
Sodii carbonatis			
Potassii carbonatis āā	5		gr. lxxv
Pulveris radicis rhei	10		ʒ ijss
Sacchari lactis	25		ʒ vi

Misce S. Half a teaspoonful every hour.

The following are intended to relieve both pyloric spasm and hyperacidity:

Elsner:

℞	Gm. or c.c.		
Extracti belladonnæ	0	1	gr. jss
Sodii bicarbonatis			
Magnesii phosphatis āā	10		ʒ ijss

Misce S. A teaspoonful three times a day.

Trousseau:

℞	Gm. or c.c.		
Extracti belladonnæ	3		
Foliorum belladonnæ āā	0	33	gr. v
Extracti gentianæ q. s.			
Fiant pilulæ. No. XXX			

Misce S. One pill before breakfast. Increase slowly to five pills.

Cohnheim:

℞	Gm. or c.c.		
Tincturæ belladonnæ	5		gr. lxxv
Olei amygdalæ dulcis (olei amygdalæ expressi)	30		℥ i
Vittellum ovi unius			
Aquam destillatam ad	200		℥ vi ʒ v
Fiat emulsum			

Misce S. Two teaspoonfuls three times a day.

Cohnheim uses the alkalies as follows: Where there is diarrhea, calcium salts; that is, calcium carbonate and calcium phosphate. Where there is constipation, magnesia usta or magnesia ammonia phosphate. Under normal conditions, sodium phosphate, sodium bicarbonate, and sodium citrate.

For direct effect on the ulcer, bismuth subnitrate and nitrate of silver still hold an important place. Cohnheim uses bismuth subnitrate for chronic ulcers in old people, and nitrate of silver in acute cases as follows:

℞	Gm. or c.c.		
Argenti nitratis	0	5	gr. viii
Aquæ destillatæ	200		gr. viii
	(dark bottle)		

Misce S. One teaspoonful (porcelain spoon), in wine-glass of distilled water, one-fourth or one-half hour before eating.

Dilute solutions of silver nitrate and ferric chlorid have been used to irrigate the stomach with the intention of influencing the ulcer directly. But when it is remembered how soon these solutions become greatly diluted or neutralized, and also that it is never known how near to perforation any ulcer may be, when one considers the distention of the stomach and the retching which frequently occurs while the stomach-tube is being passed, all will agree that this is a method of questionable utility.

External local applications are recommended by practically all authorities; cold in case of hemorrhage and during acute exacerbations, and hot in chronic cases.

All the German specialists recommend and use the balneologic treatment in cases of ulcer. When possible, the patient is sent to one of the well-known watering places, or, if this is for any reason, such as lack of means, impracticable, the waters or salts are used in the home treatment. For robust individuals the Carlsbad water or salts are used, while for those who are thin and anemic, Vichy is recommended. The Germans assert that these waters and salts owe their beneficial effects to their specific action on the glandular tissue of the alimentary tract, while some American writers maintain that the salts simply neutralize the acids present in the stomach.

In addition to these special measures directed to the ulcer, other general treatment should be applied to the constitutional condition. The results obtained by medical treatment vary greatly in different series of statistics collected by different observers. Their value is impaired by the fact that all are not observed for the same length of time, and there are a number of cases in certain series unaccounted for, the termination of which is unknown. The table of results of treatment by various men, the figures for which were collected from various sources, show how widely results of medical treatment differ:

TABLE OF RESULTS OF TREATMENT

Statistics by	Patients No.	Cured %	Improved %	Relapsed %	Died %
Sears	183	22.9	59.0	8.0	7.0
Friedenwald	287	66.0	28.0	....	1.0
Bulstrode	500	....	82.0	40.0	....
Russel	47	42.0	44.7	....	....
Schultze	291	89.0	....	....	....
Subsequently	157	53.0	23.0	15.4	7.0
Lenhartz	...	....	....	....	2.3
V. Leube	...	90.0	6.0	....	2.5
Warren	...	34.0	....	43.0	10.0

Pyloric stenosis, 10 per cent.; carcinomata, 3 per cent.

The mortality is variously estimated (in percentages) as follows:

Musser	8
Regal	from 8 to 10
Lebert	from 8 to 10
Welch	15
Leube	25
Debove and Reynolds	50

Of this last series (Debove and Reynolds), thirteen deaths were due to perforation, five to hemorrhage, twenty to intercurrent tuberculosis, five to inanition, and seven to various causes. These statistics are uniform in one respect: they indicate that at present the result of medical treatment of ulcer of the stomach is decidedly unsatisfactory.

Until the pathogenesis of gastric ulcer is made clear, and a treatment based on etiology is possible, our principal hope for better results must rest on earlier diagnosis. This will be possible when we cease to depend on subjective symptoms for diagnosis and learn to use more universally the tests for occult blood in the feces.

1720 Connecticut Avenue, N. W.

Hookworm Disease.—In regard to the many bizarre symptoms that have been ascribed to the hookworm, a remark by Dr. Byrd, assistant health officer of Florida, is apropos. "The safest rule to follow is: In all cases of anemia that cannot otherwise be satisfactorily accounted for, examine for hookworms. Don't be thrown off guard looking for dryness of hair and skin, which may be as moist as your own; protrusion of the abdomen, which may be straight as a bean pole; history of ground itch, which you may or may not get; and any other of the hundred-and-one symptoms with which the literature is teeming, but examine the stool at once for eggs and settle this question." And it may be added, after the eggs are found, be sure from blood examination, count of parasites, or improvements of symptoms after treatment that the real trouble is the hookworm before closing the case.—H. J. Nichols in *Medical Record*.

THE DUST MENACE AND MUNICIPAL DISEASES *

HOWARD S. ANDERS, A.M., M.D.
PHILADELPHIA

Among the causes of what may not inappropriately be termed municipal diseases infection, irritation and neurovascular tension play a peculiarly predominant part—most of them an obvious part; some, however, are subtle in their workings. To specify three concrete elements corresponding to and mainly responsible for or contributory to these etiologic processes, there are dust, smoke and unnecessary noise; and the one that looms largest in municipal morbidity and mortality is undoubtedly the widespread prevalence of an irritating as well as infecting dust contamination of our city atmosphere. This dust menace and nuisance is preventable, not only in the streets, as is now demonstrated in a few large cities, but likewise in our living and working places, in houses, cars, stores, factories, shops, offices, stations, theaters and churches; in fact, there is a vicious circle here in that street-dust is blown, swept and tracked into habitations, to be swept back into the streets again. Much house-dust pollution would be avoided if the original street-dust were removed or allayed. Says Dr. George A. Soper of New York: "There is something incongruous about a board of health conducting a crusade against smoke and noise and at the same time allowing the streets to be filthy with dust and dirt."

In biographic and occasional references to Benjamin Franklin, it is the usual thing to have pointed out to us his many talents and rare common sense as well as his courageous patriotism and eminent public service. It is, however, perhaps as entertaining and interesting as it is instructive and exemplary to read in the "Autobiography" of his study and efforts relative to dirty, dusty streets in Philadelphia and London, as far back as a century and a half ago. Here as elsewhere does he reveal the master mind in originality and acuity of per-ption, versatility of faculty, and prompt practicality of on. The dust evil was a seriously annoying problem him as a citizen if not as a sanitarian; to him dust was at least noisomely offensive if not infective. He writes of his proposal to Dr. Fothergill of London—whom he commends as "a great promoter of useful projects"—that "for the more effectual cleaning and keeping clean of the streets of London and Westminster," contracts be let to have the dust swept up in dry seasons, especially before the shops and windows of the houses are open, and that the gathered heaps of refuse be carried away in close-covered carts. Could Franklin view the methods and results in London, Toronto, Berlin and some other cities to-day, his only regret might be that it had taken so long to inaugurate the improvement; and that so many cities still drag along, apparently contented and unable to cope with a distressing, dust-polluted atmosphere, even worse than in his own day, by reason of the aggravations of modern speed traffic. He concludes:

> Some may think these trifling matters not worth minding or relating; but when they consider that though dust blown into the eyes of a single person, or into a single shop on a windy day, is but of small importance, yet the great number of the instances in a populous city and its frequent repetitions give it weight and consequence, perhaps they will not censure very severely those who bestow some attention to affairs of this seemingly low nature.

Now that for about seven years street-dust as an element in the propagation of disease, especially in large cities, has received such marked and spreading recognition, the problem of street as well as house cleanliness is a live and urgent one. Modern civilization, being mainly materialistic and commercialistic, is responsible for the creation of a multifarious, mixed, material refuse: street-dust is such a pernicious and persistent menace to the public health because it bodies itself forth as veritable synthetic pulverized poison composed of various more or less palpable particles of mechanical, chemical and bacteriologic substances, both irritating and infecting when inhaled.

As long ago as 1870, Tichborne and Tyndall showed that most of the particles of fine dust suspended in city atmosphere are composed of organic matter, and bacteriology has since shown that the invisible part of visible dust, that is, its germ content, is the dangerous element that calls for a drastic and determined movement for the suppression and removal of the menace everywhere. This applies mainly to cities.

Country road dust is composed principally of ground-up rock and is a comparatively clean dirt, irritating to the mucous membranes but relatively innocuous as to pathogenic organisms. Besides, the task of dust-allaying must obviously for some time to come remain a municipal one, excepting in those suburban and more populous, much-trafficked and prosperous outlying communities where even now many miles of macadamized and Telford roads are oiled, tarred, or sprinkled with water.

Apart, however, from the modicum of mineral dust arising from the wear and tear of street pavements by horse, wagon and railway-car traffic, municipal dust represents the accumulation of débris of various kinds, animal and vegetable, such as dried sputum of human origin, horse and dog droppings and slobberings, dead and disintegrated insects, scattered garbage and house sweepings, loaded vehicle losses, smoke and soot—in short, mainly an organic combination which in warm, wet weather is seething with rottenness; and in dry weather is mostly blown into our houses, noses and clothing by gusty winds, or sucked up as noxious, stifling clouds by motor cars while they speed and trolley cars while they are running or braking for a stop.

To the average pedestrian, dust is hardly more than an annoyance; hence arises the large opportunity and high duty of men in our profession to educate the public to the dangers of dust; to show that it is not simply an irritant to the eyes, nose and throat, but a serious carrier of infection by inhalation and swallowing; that the pus-producing germs, so abundant in such dust, may and do infect and produce purulent conjunctivitis, boils and carbuncles, and the graver purulent catarrhs of the nasal, faucial and bronchial tissues.

That most of the communicable diseases of the respiratory tract are produced and transmitted by dust is doubtless true. For years we have had before us the deadly relation of the dust evil to tuberculosis. Were that the only danger, surely the awful prevalence and mortality-rate of the "great white plague" would alone justify the fight for street cleanliness and a declaration of independence against dust distributers. But when one adds to this the host of other dust-borne diseases, catarrhal, tonsillar, bronchial, influenzal, pneumonic, rheumatic, cutaneous, the need for efficient public service in remedying and removing the evil becomes intensely imperative and the demand inexorable for right results.

Epidemics of purulent catarrh, tonsillitis of severe type, influenza, bronchitis, sore eyes, boils, have fre-

---

* Read before the American Climatological Association, Montreal, Canada, June 14, 1911.

quently and commonly been associated with, or have closely followed, prolonged meteorologic periods of dry, gusty weather, when it was too cold to sprinkle the dirty streets properly, or when the city authorities have been too careless in beginning the cleaning and sprinkling of streets early in the season.

Dust particles are necessary nuclei for the formation of fogs (as experimentally shown by Carl Barus) and the suspension of atmospheric moisture; and thus a twofold unhygienic relation of dust should be brought to mind. In the first place, an excessive amount of municipal dust, attracting to itself a corresponding amount of moisture, actually renders the sensible humidity of the city air more unbearable and debilitating generally. Secondly, conceding "that pathogenic organisms are adherent to particles of dust of various kinds, and that their retention of virulence depends on the amount of hygroscopic moisture with which they are associated," as Harrington points out, the more they are protected by such hygroscopic dust particles, the longer they will sustain the viability to which such moisture is essential, especially in warmer temperatures.

It is a needful thing in public health teaching to dispel the notion—the obsession it has almost become—as to "catching cold." Truly, most of the so-called "colds" are dust infections gotten in places where people congregate and traffic circulates freely, as in street cars, theaters, department stores, moving picture shows, halls, etc. As Woods Hutchinson has aptly put it, "colds" might rather be called "fouls." Human agency is principally at fault in polluting the air with disease-bearing dust, and human agency and energy must be solicited and directed to arrest, subdue and prevent its production and propagation. The so-called air-borne diseases of great cities are really synonymous with dust-borne. Instead of bad air in the vague sense, let us speak of dusty air in the definite sense; instead of the Italian malaria, the Greek derivative *konisaria* (*konis,* dust; *aer.* air).

One of the most significant discoveries of recent times in clinical medicine is the not infrequent causative relation of follicular tonsillitis to the early development of rheumatic, endocarditic and pericarditic complications and sequelæ. On first thought it may seem like a startling and incredible statement to make that dust may at times infect the tonsils, and through these portals cause the most serious and malignant involvements of joint and heart structures; and yet sufficient medical literature and my careful study of several cases demonstrate clearly that the links of the pathologic process do connect.

Dust, then, is not by any means or in the main a mere nuisance and source of public discomfort, but perforce a menace and direct public danger of deadly potentiality.

Further still, as a habitually inhaled mechanical and sometimes chemical irritant alone, dust predisposes the upper air passages to later if not occasional associated bacterial implantation because of the production of a catarrhal soil of ready receptivity and decreased local vital resistance; the germs are not only invited, but embraced and encouraged to stay, multiply and penetrate to the innermost portions of a body which is at the same time somewhat generally debilitated and vulnerable. Here again comes forth a vicious circle. The more dusty the air of our cities, and the more consequent catarrhal irritation, the more sputum, and the more people spitting promiscuously in public; and the more people spit the more infectious and dangerous the dust becomes.

The street-cleaning problem cannot be dissociated from the problem of the enforcement of anti-spitting laws. People with nasopharyngeal and bronchial catarrhs must expectorate somewhere; and for many years to come they will do so on our highways. It is practically difficult and a great hindrance to progress in this matter of preventing or lessening expectoration on our streets as long as inadequate and inefficient means and methods of street-cleaning and dust-allaying fail to control or suppress the dust evil.

As the anti-dust campaign, in Philadelphia at least, got its first impetus from the point of view of the prevention of tuberculosis, a special reference to the relation of dust to this widespread disease may be made with propriety. First, the constant inhalation of all kinds of irritating dust makes the invasion of the tubercle bacillus easy. This is well known not only as regards occupational mineral and organic dust, but particularly in respect to municipal street-dust and house-dust of ordinarily constant prevalence. General and local predisposition are coupled in that the environment conduces to the former equally with the latter. Secondly, although less commonly, direct infection with the tubercle bacillus from street-dust may occur from recently expectorated tuberculous sputum that has dried rapidly under a strong wind on a cloudy day; but habitual infections from house-dust are, of course, the usual modes. Thirdly, mixed infections with the common dust germs of pus formation, the staphylococci and streptococci, may occur as well as with the bacilli of pneumonia and influenza. It is to these that we must lay the great burden of the aggravations, complications and fatal terminations of our tuberculous patients. A simple, curable, early case becomes difficult or impossible to jugulate because of a mixed dust infection, and consequent extensive and progressive caseation and cavitation. How many hopeful, more or less curable, tuberculous patients have run a rapidly fatal course because of the daily inhalation of a foul street-dust will never be known.

Says Jacob A. Riis: "All things come to those who wait—and fight for them." The history of the agitation against the dust menace in Philadelphia, and the results obtained there to-day, while yet far from satisfactory, show that educative repetition of the facts and remedies at hand will bring about substantial improvement, and often sooner than expected, a quite rapid progress to still better conditions. In 1903, while president of the Pennsylvania Society for the Prevention of Tuberculosis, I inaugurated a campaign of publicity against the dust evil, particularly as related to the dirty streets and cars. For two years more the attention of the public was called to the dangers of dust, and an endeavor made to have the proper municipal authorities adopt and practice modern means and methods of street-cleaning and dust-allaying. The Philadelphia Rapid Transit Co. (which operates all the trolley-cars in the city) responded to the agitation by abolishing the foul, dusty plush cushions. The city officials were inclined to resent interference with their inertia and indifference, but the criticisms began to tell to the extent that sporadic attempts at better cleaning and sprinkling of streets were made at irregular intervals.

In January, 1909, as chairman of the legislative committee of the society, I took up the work with renewed vigor. Attention was again called to the disease-predisposing and infecting dangers attaching to the actually filthy condition of the streets, and to the stupid, ill-timed, incompetent ways of attempting to clean them; a dry dabbling method of sweeping, in spots at that, with no preliminary thorough sprinkling or flushing of the asphalt pavement, and this done in daytime in the most frequented streets, causing clouds of dust to be raised to annoy and to endanger thousands of pedestrians. Also the heaps of sweepings, even when moist, were allowed to remain for hours and become dried by the sun and the wind, and usually scattered about again by air-gusts and automobiles. Public opinion began to recognize that such slipshod, lackadaisical inefficiency was due to an inexcusable irresponsibility, if not a shameless cupidity on the part of officials and contractors who could thus disregard public health.

Simultaneously I issued circular letters of queries to the mayors of some twenty-five cities of America and Europe as to the methods and results of cleaning, dust-reducing, and keeping clean the streets of their respective jurisdictions. The replies from the principal cities were tabulated and afforded a basis for a comparative study of the situation, and the results were published in the spring months of 1910 in a series of twelve articles in a few of the newspapers of Philadelphia, mostly in the *Public Ledger*. The cities reporting were twenty-one, including Philadelphia, and stated the requirements of ordinances, what was actually done and how, and with what degree of satisfaction and sanitary safety, according to official opinion. To enumerate the cities alphabetically, there were Baltimore, Buffalo, Birmingham (England), Berlin (Germany), Budapest (Hungary), Cleveland, Denver, Detroit, Dublin (Ireland), Leipsic (Germany), London (England), Minneapolis, New Orleans, New York, Paris (France), St. Louis, Stuttgart (Germany), Toronto (Canada), Vienna (Austria), and Washington, D. C. I was able to supplement these reports by personal observation in some of these cities and in Munich, Germany. To summarize:

1. In a majority of the cities where results were satisfactory, the principal cleaning was done at night, or completed before 6 o'clock in the morning.

2. Thorough sprinkling preceded sweeping. Sprinkling was also done two to four times daily in dry (non-freezing) weather to lay prevalent dust.

3. Flushing wagons or flushing from curb to curb with hose is the method used in preference to sprinkling and machine sweeping in the best cleaned cities. Indeed, sprinkling is seldom necessary where the streets are thus virtually washed two or three times weekly.

4. Hand sweeping by blockmen in day-time is always preceded by wetting with a hand sprinkler.

5. Piles of dirt are immediately removed while wet or damp in covered wagons.

6. Last, but by no means least—and the method which in my judgment is destined before long to supersede all others in street cleaning—is the dustless operation of dust and dirt removal by automobile vacuum street-cleaners, on the principle of vacuum housecleaning which is now rapidly taking the place of the old dirty, dust-raising broom and feather-duster. Recent tests of these street machines have developed the fact that in one hour as much surface can be actually cleaned as was imperfectly gone over with dusty accompaniments by horse-drawn sweepers in six hours.

It was pointed out by contrast that in Philadelphia and some other cities it was adding insult to injury to attempt to clean the streets by methods that aggravated instead of mitigated the dust evil, discomfort and danger. Sprinkling before sweeping was specified in contract but never carried out. Hence the criticism was urged that not only better means and methods needed to be adopted, but more systematic and adequate inspection and supervision of the work done and the methods specified, and a more efficient management generally by the city street-cleaning officials, whether the work was done by the government or by contractors. Otherwise, it was futile and farcical to expect a lessening of the menace of dust. The blame for dirty streets should not be placed entirely on the day laborer who may shirk his job. He is only following an example higher up.

The people were appealed to in these articles, and a public protest sought. If they were insistent and persistent in their demands for clean streets, the city government would be equally insistent in its demand on the contractors. The public was reminded that streets are the ventilating flues of cities, and as a result house ventilation depends much on the purity and quality of street air; whereas, dirty, dusty streets become aboveground air sewers instead of pure air channels.

It soon became evident that a dust-infected people was becoming discontented, and that a city healthful was of greater importance than a city beautiful; in fact, that civic cleanliness made for civic beauty and art. Taxpayers began to realize that they were not receiving an equity of public sanitary safety.

Education has been telling, and the street-cleaning authorities have been seeing a great light in Philadelphia. The methods have improved; the work is more efficiently done; flushing wagons have recently been introduced with effectiveness, but of course too few as yet, and capable of attending to no more than a half dozen of the busy down-town streets. A steady, strong fan-shaped column of water is driven laterally by the pressure of a gas-engine on the rear of the wagon so that all débris is flushed into the gutters from the middle and sides of the streets; the wagons are horse-drawn, passing in pairs, one a little in advance of the other; the streams of water being directed in opposite directions.

It is a hopeful sign of the awakening of the public to demands for civic cleanliness, that officialdom is beginning to respond in a readier performance of its duty and responsibility in safeguarding the public health and incidentally safeguarding respect for law, order and government. To avoid an insurrection of the citizenship, there must needs be a resurrection of statesmanship.

BANTI'S SYMPTOM-COMPLEX

WITH REPORT OF A CASE*

J. F. HULTGEN, M.D.
CHICAGO

Patient.—A. H., aged 35, druggist, was admitted to the Englewood Hospital, Nov. 3, 1910. He is a patient of Dr. Charles Piper, through whose kindness I am allowed to study this case.

History.—Sick, or sickly, a good deal; always delicate and pale, but without history of any definite disease until eight years ago, when he contracted syphilis, for which he was treated as well as his rather free habits would permit. Three years ago he consulted Dr. Belfield, who observed the splenomegaly, and advised further energetic antiluetic therapy. The patient used tobacco moderately, and alcohol to excess at intervals; denied any drug addiction.

Examination.—Patient was a thin, icteroid, emaciated, sickly-looking man, with large abdomen, very pale visible mucous membranes and without fever. With all these objective symptoms, he seemed rather optimistic. He complained of great weakness, but no pain, vomiting, nausea, or headache. Appetite was poor; patient had diarrhea for last two or three days before admission; no hemorrhage at any time. Fingers and tongue were tremulous; speech showed some stuttering. Tongue moist, slightly furred; gums pale, yet intact. Pupillary reflexes were negative; patellars exaggerated. Quinquaud's sign present. The lungs, joints, glands and throat were negative. The heart showed a small bruit over the apex; systolic, short, not transmitted to the left; no cardiac hypertrophy, no arrhythmia. Pulse 84, of rather low tension; no basal pulmonary congestion; no edema of the legs. The abdomen was prominent, walls thin; skin smooth, but not discolored. There was a distinct bulging of the left hypochondrium, and moderate prominence of the right upper abdomen. Movable dulness; succussion thrill and ballottement of upper abdominal organs left no doubt as to the presence of a large amount of free fluid in the belly cavity. The spleen was very large, hard, moderately movable and slightly tender; its free border felt distinctly notchy. It extended to a full hand's breadth below the left costal border. The upper splenic border was at its normal level, and the organ showed no sign of ptosis. The liver was distinctly enlarged; its edge was rather dull and a trifle irregular; it was not tender to ordinary pressure. There was no special tenderness over the gall-bladder.

---

* Read in the Section on Pathology and Physiology of the American Medical Association, at the Sixty-Second Annual Session, held at Los Angeles, June, 1911.

The urine showed no bile, no albumin, no sugar; distinct reaction for urobilin.

The blood: reds, 2,100,000; distinct poikilocytosis; no polychromatophilia, no nucleated reds. Hemoglobin, 45 per cent. (Tallquist). Whites: 2,600. Differential: polynuclears 77.8 per cent., small mononuclears 15.7 per cent., large mononuclears 4.5 per cent., eosinophils 2 per cent.

Course.—The patient gradually gained in appetite, strength and appearance. His weight began to improve slowly, hand in hand with the recession of the ascites and the diminution in size of the spleen and liver. Moderate subicterus remained. His progress may be traced graphically in Chart 1. The treatment consisted in mixed mercury and iodid of potassium medication. In April three successive doses of sodium cacodylate were given by intramuscular injection, but this arsenic therapy was abandoned because of the marked intolerance to it. Mr. A. H. had been able to attend to light professional duties and his condition on May 18, 1911, showed the following symptoms: "Subicteric, yet pale, rather thin; tremulous lips and fingers. Eats and sleeps fairly well, but tires easily and lacks ambition. No headache, no eye or ear troubles; no hemorrhages, and no pains. Ascites greatly diminished, liver and spleen just palpable. Urine shows urobilin, no bile, no albumin, no sugar; microscopically negative. Wassermann reaction (Dr. Mefford) positive.

"Blood: reds, 3,600,000; moderate poikilocytosis, no nucleated reds, no polychromatophilia; hemoglobin 90 per cent. (Tallquist). Whites, 5,300. Differential: polynuclears 57.6 per cent., small mononuclears 37.7 per cent., large mononuclears 3.8 per cent., eosinophils 0.9 per cent. No abnormal cells."

Patient was planning how he could earn more money, and a few days later he entered on a new occupation, which required considerable physical and mental exertion. After a week, his condition had aggravated again; a rather severe gastro-enteritis (*Brechdurchfall*) occurred, a slight exacerbation of the icterus without acholic stools, and fever, rather rapid pulse and severe headache. The blood-curves show the deterioration of his hematopoietic system. A few nucleated red blood-cells appeared and the poikilocytosis increased (see Chart 1). Three weeks afterward he was again improving.

INTERPRETATION OF THE ANAMNESTIC, CLINICAL AND HEMATOLOGIC FINDINGS IN THIS CASE

A man who always had been frail and sickly, without any history of purpura or of hemorrhage, contracted syphilis eight years ago and was treated for it in the usual way. His splenomegaly was recognized two years ago (Dr. Belfield). There is no history of any antecedent marked icterus. The patient's habits readily suggested alcoholic cirrhosis as a primary diagnosis, and a cursory physical examination seemed to confirm it. Repeated, careful blood-counts, however, led to further examinations, and to the recognition of a symptom-complex characteristic of splenic anemia.[1] A brief review of the clinical, pathologic and hematologic data of such cases shows at once the scarcity of diagnostic criteria.[2] Yet on serious reflection it seems to me that the splenomegaly is the central figure in the clinical picture of these anemias, and that the name of Banti's symptom-complex fits the disease better, and emphasizes better Banti's splenogenic[3] theory than any other. By this I mean to accept in their widest meaning Dock and Warthin's,[4] and Warthin's[5] finding of phlebosclerosis, and calcareous degeneration of the splenic and portal veins, which they explain as following a primary thrombosis of these blood-vessels. Theirs is the merit to have called attention to the rôle of splenic and portal phlebosclerosis as an etiologic factor in this symptom-complex, but they fail to suggest an antecedent endophlebitis as the initial lesion in this vicious circle. This seems to me more probably the case, since in the first ten days of typhoid fevers there is an almost identical blood-picture with splenomegaly, and some oligocythemia. The early generalized endothelia-cell hyperplasia, according to Mallory one of the characteristics of typhoid fever pathology, accounts for the frequent phlebothromboses occurring in these affections. The toxin-laden venous blood irritates the endothelial cells of the walls of the veins, and thus conduces to thrombosis, venous stasis, passive hyperemia, irritation of the reticulum, or stroma, or both, with subsequent disturbance of the splenic functions. The question as to whether in splenic anemia the plastic or the lytic functions of the spleen[6] are

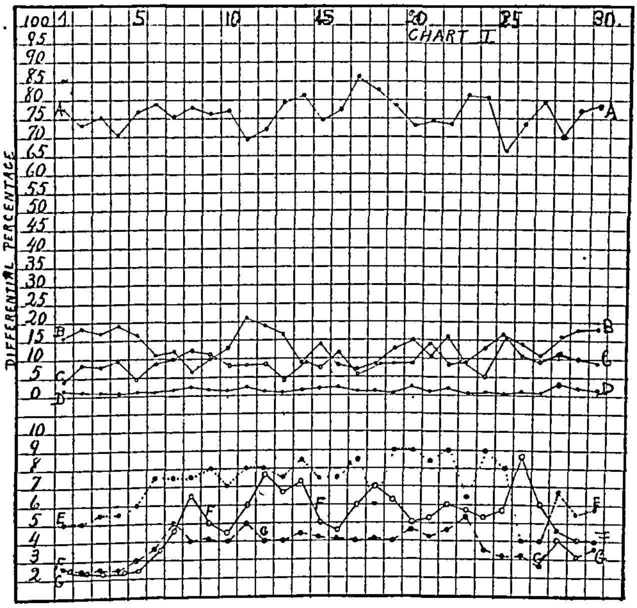

Fig. 1.—Chart showing blood-picture of splenic anemia. Thirty consecutive counts in one case. A indicates polynuclears; B, small mononuclears; C, large mononuclears; D, eosinophils; E, hemoglobin; F, total whites; G, total reds. The column to the left indicates differential percentages. Note (1) the constant parallelism between the curves of hemoglobin, white blood-cells and red blood-cells; (2) the very frequent synchronous movements, and (3) the uniformity of each curve in both charts.

individually or jointly involved cannot be settled as yet, but the study of the foregoing shows that the curves of the red blood-corpuscles, of the hemoglobin, and of the total leukocytes show distinctly parallel and mostly synchronous movements. This, I can interpret, not as signs of hematolysis, but of a slow or bradyplastic hematopoiesis, as a disturbance of the entire blood-forming system. The splenomegaly is due to an active irritative inflammation of Malpighian bodies and of the stroma. Bradyhematopoiesis is, in my opinion, the underlying hematologic basis of the Banti symptom-complex. It is sluggish production of blood, due to antecedent impoverishment of the blood-forming tissues, especially of the spleen, that we have to deal with here, not an anhematopoiesis as Auburtin[7] thinks. Splenic anemia is not an objectionable term, Naegeli's[8] and others' opinion notwithstanding; it designates a symptom-complex which is more closely akin to pernicious anemia[9] than to leukemia.

The fact that splenic endophlebitis in my case is of luetic nature, as in that of Willy Schmidt's,[10] or of kala-azar spirochetic origin, as in Marchand's case,[1] should in no way prevent us from considering the splenomegalic anemia as a clinical entity, just as a nephritis retains its identity no matter what its etiology may have been. It is hardly probable that splenic anemia may be a dormant leukemia.[12] On the contrary, I believe it to be the last stage of an extinct leukemia, hence its lack of permanent recuperability, and its striking rarity in children. My charts show that at no time during the course of splenic anemia does the blood become normal in all of its ingredients; either the erythrocytes, leukocytes or the hemoglobin are subnormal, singly or together (see charts). Reasoning *a priori*, Banti's disease must be rare in childhood, on account of the resiliency of the hematopoietic system in children. In fact, Weil and Clerc never saw a case of this in a child.[13] The same hematopathic cause would produce in a child an anemia infantum pseudoleukemica of von Jaksch. If, then, the Banti symptom occurs so rarely or not at all in childhood, it is well to add that a von Jaksch anemia in a child is the equivalent of a splenic anemia in the adult for reasons detailed above. It must, however, be kept in mind that a strict clinical or hematologic separation from another of primary blood-diseases is often impossible. Their relation is often close and plainly evident, as can be seen from the following short classification of the generalized primary affections of the hematopoietic system. These I have divided according to their essential hematology, and subdivided according to their etiology and clinical course.

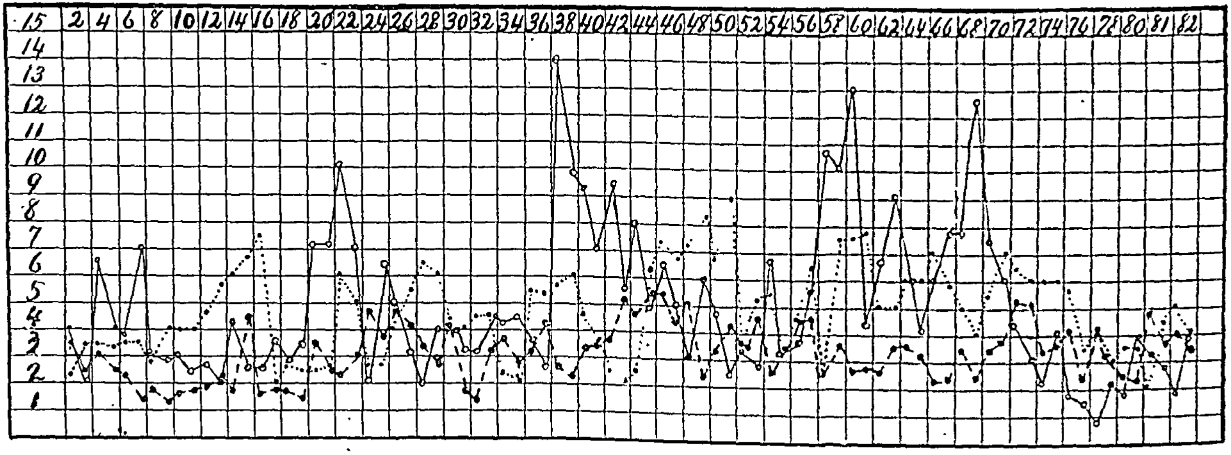

Fig. 2.—Chart showing eighty-two hemoglobin, total red and white counts determined from the literature. Line of small and large solid dots indicates hemoglobin; in percentage units broken line with solid dots, total red blood-cells, in million units; solid line with hollow dots, total white blood-cells, in thousand units. Notice that the blood-picture of Banti's symptom-complex remains pathologic throughout, *in one or more of its ingredients*.

CLASSIFICATION

1. Polycythemias: With splenomegaly.
   Without splenomegaly.
   - *a*. Idiopathic, primary (Vaquez).
   - *b*. Secondary.
2. Anemias.
   - *a*. Idiopathic, primary, essential (Addison).
     Plastic.
     Hyperplastic.
     Aplastic.
   - *b*. Secondary, pernicious, progressive (Biermer).
     Plastic.,
     Hyperplastic.
     Aplastic.
3. Ictero-anemias.
   - *a*. Acquired, hemolytic (Widal).
   - *b*. Congenital (Minkowski-Chauffard).
   - c. Congenital,[14] family-type (Gaucher).
4. Splenic anemias (Griesinger).
   - *a*. Primary, splenomegalic or Banti's disease.
   - *b*. Secondary, splenomegalic, kala-azar malarial, syphilitic, etc.
   - c. Leukanemia (v. Leube), combining the features of pernicious anemia and leukemia, alternately or conjointly.
5. Pseudoleukemias (Cohnheim) or aleukemias.
   - *a*. Anemia infantile, pseudoleukemic (v. Jaksch).
   - *b*. Lymphatic, idiopathic, pseudoleukemia or Hodgkin's disease.
   - *c*. Secondary, tuberculous, lymphatic pseudo-leukemia or Sternberg's disease.

6. Leukemias (Virchow).
    - *a.* Lymphocytic: Small.
      Large, or Rieder form.
    - *b.* Myelocytic.
    - *c.* Polynuclear.
    - *d.* Mixed.
    - *e.* Chloroma: Lymphocytic.
      Myelocytic.

The above classification of primary blood-diseases is intended to give a general comprehensive view of the generic relationship between all of them. It will also show the central position of splenic anemias, between those primary blood-affections involving the erythrocytes exclusively, mainly or partially, and those involving the leukopoietic tissues, such as the leukemias and pseudoleukemia. It is evident that the spleen plays an active rôle here[15] and not a neutral one. In point of frequency, Banti's disease holds a middle place as can be learned from my statistics, from cases seen in consultation or in my private practice from October, 1904, to June 20, 1911. Of thirty-nine cases of primary hematopathic diseases, there were thirteen of pernicious anemia, eight of splenic anemia, eight of leukemia, six of infantile pseudoleukemic anemia (von Jaksch), two cases of acquired hemolytic icterus, one case of Sternberg "peculiar" lymphatic tubercular pseudoleukemia, and one case of leukanemia. About 20 per cent., or eight out of thirty-nine primary blood-affections in my practice were of the Banti symptom-complex.

Its course is of intermittent character, as first observed by Strumpell.[16]

The diagnosis rests on the presence of the splenomegaly, the anemia with leukopenia, and the ascites. Any case with hematologic findings leaning repeatedly toward leukemia should not be included under splenic anemia. The prognosis as to life in Banti's symptom-complex is fair when the blood-picture occupies and retains its central position, but becomes rapidly bad in the proportion as it recedes from its center to one or the other extreme.

The therapy of splenic anemia, to judge from my case, should be conservative, although Sutherland and Burghard, as well as Banti,[17] were in favor of splenectomy. The undoubtedly generic nature of this symptom-complex calls for further study of the mechanism of the various hematopathic findings. The parallelism and synchronicity of the erythrocytic, leukocytic and hemoglobin curves, the absolute fatality of the disease, the intermittent and very chronic course of the affection argue not for an infectious process, but for a cause organic and anatomic in nature, and of unknown origin.

THE PATHOGENESIS OF CARDIAC HYPERTROPHY AND MYOCARDITIS *

LEO LOEB, M.D., and MOYER S. FLEISHER, M.D.
ST. LOUIS

In several former papers[1] we described a simple method which permitted us with great certainty to produce a combination of hypertrophic and myocarditic changes within a relatively short time in the heart of the rabbit. At the same time we suggested an explanation of these phenomena without, however, going into any detailed discussion regarding the basis for our theoretical conceptions. Inasmuch as it appears to us that the principle underlying our explanation of the phenomena observed in the rabbit may, perhaps, be extended to the pathology of the heart in man, we believe that a somewhat more detailed discussion of our theory might be of advantage.

The method employed by us in the production of hypertrophic and myocarditic changes in the heart of rabbits was, briefly, as follows: We injected into the ear-vein of a rabbit a single small dose of epinephrin (0.2 c.c.) preceded by spartein sulphate or caffein sodium benzoate. We found macroscopic changes in the heart muscle a few days after the injection, which, however, were most marked ten to fourteen days after the injection. Shortly after the injection slight interstitial edema was found in the heart, and somewhat later the muscle fibers showed slight increase in size. Several days after the injection, the muscle fibers were distinctly increased in size and their nuclei were also larger; the connective tissue between the muscle fibers was increased in quantity.

In the next few days the changes became more pronounced. The separation of the muscle fibers due to edema was now marked. In places we found degenerative changes in the muscle fibers; some of the fibers appeared to have been dissolved, only a thin ring of muscle substance surrounding the nucleus; the striations were now indistinct in the fibers.

About two weeks after the injection the changes had reached their maximum. The connective tissue increase was diffuse. The degenerative changes in the muscle proper had become more extensive. Besides a larger number of the muscle fibers and their nuclei were increased in size, and frequently double nuclei were seen in the muscle cells.

From this period onward the changes became less marked, both macroscopically and microscopically. The hypertrophy of the muscle fibers and muscle nuclei gradually disappeared; the degenerative changes were no longer apparent. Finally, twenty weeks after the injection, small islands of fibrous tissue which had supplanted the degenerated muscle fibers were the only remaining evidences of the hypertrophy of the heart and myocarditis.

The explanation which we offered was based on certain experiments carried out on striated muscle by several investigators.

Ranke,[2] who studied the influence of tetanic contraction on muscles, found that muscles tetanized by either strychnin or a galvanic current showed an increased content of water. This larger percentage of water be considered to be due to increased imbibition and decreased resistance to the passage of water into the muscle. *This change in the water content of the muscle* was supposed to be due to an increase in dissociated products within the cells caused by the activity of the muscle.

[2] Ranke: Tetanus, Leipsic, 1865.

Cooke[3] later found that in tetanized muscles, in muscles fatigued by carrying a load, or even muscles which had been exposed to a single electric shock, the osmotic pressure was increased, such muscles taking up water from a solution hypertonic to normal resting muscles. This author further showed that this increase in osmotic pressure was not due to the electric stimulation as such, nor was the taking up of water due to the stretching of the interstitial spaces.

Fletcher[4] obtained results which, in the main, were similar to those of Cooke. He found that fatigue increased the osmotic pressure of muscles, but his findings differed from those of Cooke, as far as the subsequent curve representing the movement of water into the muscle and the influence of various strengths of solutions on the rate at which fluid was taken up were concerned.

In regard to the principal fact, namely, the taking up of water by fatigued muscles, and in regard to the increased osmotic pressure of fatigued muscles, the three authors mentioned were in agreement. On the basis of these facts and other observations which had proved that the growth of plant cells depends on an increase in turgor, and that also the growth of cells in lower animals depends on an increased taking up of water. J. Loeb[5] explained the hypertrophy of muscles resulting from increased work as due to the taking up of water following catabolic processes in the muscle leading to an increase in osmotic pressure. He also suggested that hypertrophy under pathologic conditions, in which no increased activity had preceded the hypertrophy, might be explained in a similar manner.

We assumed that as a result of the excessive work done by the heart muscle following the injection, the osmotic pressure of the muscle and consequently the movement of water into the muscle fibers was increased. After the period immediately following the injection, the conditions in the experiments performed with striated muscles *in vitro* differ from the conditions prevailing in our experiment. In the former case, the muscle was kept *in vitro* under abnormal conditions and the fatigued muscle no longer performed any work. In our experiments the muscle remained in the body, was perfused with normal blood and continued to perform work. These differences might explain the further changes found in our experiments.

We must assume that the continued work of a muscle that has taken up an abnormal amount of water may lead to further taking up of water and to processes of vacuolization and solution in some muscle fibers. This excessive effect may, therefore, lead to degenerative changes. The primary interstitial edema and perhaps the stretching of connective tissue fibers may lead to the early increase of interstitial tissue, which we found—the later increase in connective tissue being secondary to the parenchymatous changes in the muscle fibers. The increase in connective tissue and consequent shrinking of the fibrous tissue causes pressure on the muscle fibers and may thus lead to secondary parenchymatous changes in the latter.

Before we proceed further, let us consider in what other way it might be possible to explain the facts *observed by us experimentally. First, it might* be assumed that epinephrin causes changes in the heart, not through its action on the heart muscle, but by causing a contraction of the coronary vessels, thus indirectly interfering with the nourishment of the myocardium. Some facts might be cited in favor of such an interpretation. In the first place, it is well known that epinephrin causes a constriction of small arteries. It is also an established fact that a partial or complete occlusion of the coronary vessels produces degenerative and fibrous changes in the heart muscle. Plausible as this explanation may appear, it does not seem to us to be tenable. In the first place, the experimental evidence points very strongly to the conclusion that epinephrin does not cause a constriction of the coronary vessels.

Schaefer,[6] who studied the outflow of blood from the coronaries, was unable to demonstrate any influence of epinephrin on these vessels. Langendorff[7] found that this drug caused dilatation of cut-out strips of the coronary vessels of sheep and his results were confirmed by Pal;[8] DeBonnis and Susanna[9] also confirmed these results. They found dilatation of strips of coronary vessels in the majority of their experiments, in a few experiments, however, no influence of epinephrin being evident. Wiggers,[10] who studied the rate of outflow of blood from the coronaries in the resting heart, concluded that epinephrin caused contraction of the coronary vessels. Bond[11] and Campbell,[12] however, have been unable to demonstrate a constricting influence of this drug on the coronary vessels.

In view of the results of the large majority of these investigators, it is very probable that epinephrin does not cause a constriction of the coronary vessels, and that accordingly, it cannot interfere with the nutrition of the cardiac musculature.

We may, therefore, conclude that epinephrin does not cause a constriction of the coronary vessels, and that there exists no basis for the assumption that epinephrin produces myocarditis through its action on the coronary vessels. There are other facts which likewise seem to us to preclude such an interpretation. In the first place, whenever myocarditic lesions exist as a result of occlusion of the coronaries, the region near the apex is affected much more frequently than the base, while the lesions caused by epinephrin are almost exclusively found at the base of the ventricle.

Furthermore, the character of the lesion does not seem to us to be compatible with such an origin. After an acute occlusion of the coronary arteries infarct-like changes are found; at a later period fibrous tissue takes the place of the injury; while in our experiments the primary changes consisted in an increase in volume of the fibers and in the number of muscle nuclei accompanied by an increase of connective tissue.

A direct toxic action of epinephrin on the heart muscle has also to be considered as a possible explanation, especially as it is very probable that the necroses found in the media of the aorta after numerous injections of epinephrin are due to a direct toxic action on the media of the vessel, and, indeed, one of us[13] upheld such an interpretation on a former occasion. Especially might such an interpretation appeal to us in cases in which, after repeated injections of epinephrin, degenerative changes are found both in the aorta and heart. Here it might be held that a toxic action has been exerted on both organs. Nevertheless, it seems to us that this explanation is not applicable in the case of our experiments, in which, after one single injection of epinephrin, marked changes were found in the heart muscle.

Again, the situation of the lesion at a place where the muscle fibers are exposed to the greatest strain after injection of epinephrin, as well as the character of the lesion in which degenerative processes in the parenchyma are not the principal changes, seem to us to make such an explanation unsatisfactory, although we do not wish to exclude a direct toxic action of epinephrin as a contributing factor. It seems to us, therefore, that in the case of the experimental lesions of the rabbit, the theory advanced by us is the most satisfactory.

We conclude, then, that mechanical strain with its physico-chemical sequels is responsible for both the cardiac hypertrophy and myocarditic changes in the rabbit's heart.

Let us now briefly consider how far our observations and theoretical considerations are applicable to certain pathologic conditions found in man. Here, also, we find a combination of hypertrophy of the heart muscle and interstitial changes, especially increase in connective tissue in a similar manner as in the experimental lesions of the rabbit. Sometimes, the hypertrophy represents by far the more important change; at other times, the connective tissue increase is quite marked. Accordingly, these conditions are designated as hypertrophy of the heart muscle and as chronic myocarditis. In most cases, a combination seems to be present, and it is doubtful whether a sharp division between these two conditions can be maintained.

The same combination of changes is found in the experimental lesions of the heart of the rabbit. Here are noted, just as in the human heart, certain nodular areas of connective tissue overgrowth, especially at somewhat later stages, at a time when the acute lesions have retrogressed to a great extent. In the rabbit's heart we find this condition as the result of strain. The same holds good, to a great extent, in the case of the human heart. We find these changes in persons in whom the heart has to do excessive work in order to overcome increased resistance as in cases of valvular lesions, arteriosclerosis, kidney lesions. It is also possible that in cases in which, under the influence of bacterial or non-bacterial poisons, apparently a dilatation of the heart is primary, the subsequent hypertrophic and myocarditic changes owe their origin to the increase in work to which such hearts are subject in consequence of the dilatation.

There exist, however, some differences between the conditions found in the rabbit's heart and in hypertrophy and myocarditis in man. In the former, the parenchymatous degenerative changes in the muscle cells are more prominent than in the latter. This difference is, perhaps, due to the acuteness of the change in the heart and to the excessive strain, extending over a brief period only in the rabbit, while in man the strain is more chronic, extending over a long period and is usually less at any given time. In the latter we might, therefore, expect the hypertrophic and interstitial changes to prevail. We have, however, seen that also in the case of the rabbit the degenerative parenchymatous changes disappear relatively rapidly, leaving merely some fibrous bands. We may, therefore, assume that in man degenerative parenchymatous changes which perhaps existed at given times—and such changes are occasionally found in cases of hypertrophy—will heal within a brief period of time, leaving behind fibrous nodular bands.

Some pathologists ascribe the cardiac hypertrophy proper to the increased strain, while they interpret the interstitial changes as invariably due to the malnutrition of the muscle, caused by partial or complete occlusion of the coronary vessels. We have shown that in the case of the rabbit's heart in which changes are found similar to those in the human heart, the occlusion of the coronary vessels cannot be held responsible for the myocarditic changes. There we have a uniform cause leading to both hypertrophy and myocarditis. It seems to us that these facts suggest a similar uniform pathogenesis in many cases in which hypertrophy of the heart and myocarditis are combined in man. This, of course, does not exclude the possibility that in other cases partial occlusion of the coronary vessels is responsible for myocarditic changes, nor does it exclude the possibility that toxic substances may likewise cause myocarditic changes.

We believe that attention ought to be drawn to the similarity existing between the experimental lesions in the rabbit's heart and a large class of lesions found in the human heart, and that a similar pathogenesis may be suggested for both sets of conditions, the cardiac hypertrophy and the myocarditic changes.

DIFFUSE SEPTIC PERITONITIS FROM APPENDICITIS

STATISTICS OF 194 CASES

RUSSELL S. FOWLER, M.D.
BROOKLYN

To November, 1910, there came under my care 194 patients with diffuse septic peritonitis from appendicitis of whom 138 recovered, a recovery percentage of 71, and fifty-six died, a mortality percentage of 29. In this series there were at times as many as fifteen consecutive cases without a death. All patients were operated on except six who were actually moribund. An attempt has been made through a study of the 188 cases with operations to reach some conclusion as to the value of the different methods of treatment in diffuse septic peritonitis following appendicitis. It is interesting to note that in eighty-three cases in which treatment consisted of the administration of fluids by mouth, saline enemas every three or hour hours, with the Fowler position, sixty patients recovered, a recovery percentage of 72.3, and twenty-three patients died, a mortality percentage of 27.7. In a series of thirty-nine patients treated by the elevated head and trunk position, the administration of fluids by mouth and nothing by rectum, thirty patients recovered, a recovery percentage of 76.9, and nine died, a mortality percentage of 23.1. Combining the statistics in these two series we have a series of 112 cases in which the elevated head and trunk position was used and fluids were given by mouth; eighty-three of the patients received enemas and thirty-nine nothing by rectum. Of these patients thirty-two died, showing a recovery percentage of 72. Comparing these three sets of figures it would seem that the administration of fluids by rectum had little if any influence on the after-course.

water he considered to be due to increased imbibition and decreased resistance to the passage of water into the muscle. This change in the water content of the muscle was supposed to be due to an increase in dissociated products within the cells caused by the activity of the muscle.

Cooke[3] later found that in tetanized muscles, in muscles fatigued by carrying a load, or even muscles which had been exposed to a single electric shock, the osmotic pressure was increased, such muscles taking up water from a solution hypertonic to normal resting muscles. This author further showed that this increase in osmotic pressure was not due to the electric stimulation as such, nor was the taking up of water due to the stretching of the interstitial spaces.

Fletcher[4] obtained results which, in the main, were similar to those of Cooke. He found that fatigue increased the osmotic pressure of muscles, but his findings differed from those of Cooke, as far as the subsequent curve representing the movement of water into the muscle and the influence of various strengths of solutions on the rate at which fluid was taken up were concerned.

In regard to the principal fact, namely, the taking up of water by fatigued muscles, and in regard to the increased osmotic pressure of fatigued muscles, the three authors mentioned were in agreement. On the basis of these facts and other observations which had proved that the growth of plant cells depends on an increase in turgor, and that also the growth of cells in lower animals depends on an increased taking up of water, J. Loeb[5] explained the hypertrophy of muscles resulting from increased work as due to the taking up of water following catabolic processes in the muscle leading to an increase in osmotic pressure. He also suggested that hypertrophy under pathologic conditions, in which no increased activity had preceded the hypertrophy, might be explained in a similar manner.

We assumed that as a result of the excessive work done by the heart muscle following the injection, the osmotic pressure of the muscle and consequently the movement of water into the muscle fibers was increased. After the period immediately following the injection, the conditions in the experiments performed with striated muscles *in vitro* differ from the conditions prevailing in our experiment. In the former case, the muscle was kept *in vitro* under abnormal conditions and the fatigued muscle no longer performed any work. In our experiments the muscle remained in the body, was perfused with normal blood and continued to perform work. These differences might explain the further changes found in our experiments.

We must assume that the continued work of a muscle that has taken up an abnormal amount of water may lead to further taking up of water and to processes of vacuolization and solution in some muscle fibers. This excessive effect may, therefore, lead to degenerative changes. The primary interstitial edema and perhaps the stretching of connective tissue fibers may lead to the early increase of interstitial tissue, which we found—the later increase in connective tissue being secondary to the parenchymatous changes in the muscle fibers. The increase in connective tissue and consequent shrinking of the fibrous tissue causes pressure on the muscle fibers and may thus lead to secondary parenchymatous changes in the latter.

Before we proceed further, let us consider in what other way it might be possible to explain the facts observed by us experimentally. First, it might be assumed that epinephrin causes changes in the heart, not through its action on the heart muscle, but by causing a contraction of the coronary vessels, thus indirectly interfering with the nourishment of the myocardium. Some facts might be cited in favor of such an interpretation. In the first place, it is well known that epinephrin causes a constriction of small arteries. It is also an established fact that a partial or complete occlusion of the coronary vessels produces degenerative and fibrous changes in the heart muscle. Plausible as this explanation may appear, it does not seem to us to be tenable. In the first place, the experimental evidence points very strongly to the conclusion that epinephrin does not cause a constriction of the coronary vessels.

Schaefer,[6] who studied the outflow of blood from the coronaries, was unable to demonstrate any influence of epinephrin on these vessels. Langendorff[7] found that this drug caused dilatation of cut-out strips of the coronary vessels of sheep and his results were confirmed by Pal;[8] DeBonnis and Susanna[9] also confirmed these results. They found dilatation of strips of coronary vessels in the majority of their experiments, in a few experiments, however, no influence of epinephrin being evident. Wiggers,[10] who studied the rate of outflow of blood from the coronaries in the resting heart, concluded that epinephrin caused contraction of the coronary vessels. Bond[11] and Campbell,[12] however, have been unable to demonstrate a constricting influence of this drug on the coronary vessels.

In view of the results of the large majority of these investigators, it is very probable that epinephrin does not cause a constriction of the coronary vessels, and that accordingly, it cannot interfere with the nutrition of the cardiac musculature.

We may, therefore, conclude that epinephrin does not cause a constriction of the coronary vessels, and that there exists no basis for the assumption that epinephrin produces myocarditis through its action on the coronary vessels. There are other facts which likewise seem to us to preclude such an interpretation. In the first place, whenever myocarditic lesions exist as a result of occlusion of the coronaries, the region near the apex is affected much more frequently than the base, while the lesions caused by epinephrin are almost exclusively found at the base of the ventricle.

Furthermore, the character of the lesion does not seem to us to be compatible with such an origin. After an acute occlusion of the coronary arteries infarct-like changes are found; at a later period fibrous tissue takes the place of the injury; while in our experiments the primary changes consisted in an increase in volume of the fibers and in the number of muscle nuclei accompanied by an increase of connective tissue.

A direct toxic action of epinephrin on the heart muscle has also to be considered as a possible explanation, especially as it is very probable that the necroses found in the media of the aorta after numerous injections of epinephrin are due to a direct toxic action on the media of the vessel, and, indeed, one of us[13] upheld such an interpretation on a former occasion. Especially might such an interpretation appeal to us in cases in which, after repeated injections of epinephrin, degenerative changes are found both in the aorta and heart. Here it might be held that a toxic action has been exerted on both organs. Nevertheless, it seems to us that this explanation is not applicable in the case of our experiments, in which, after one single injection of epinephrin, marked changes were found in the heart muscle.

Again, the situation of the lesion at a place where the muscle fibers are exposed to the greatest strain after injection of epinephrin, as well as the character of the lesion in which degenerative processes in the parenchyma are not the principal changes, seem to us to make such an explanation unsatisfactory, although we do not wish to exclude a direct toxic action of epinephrin as a contributing factor. It seems to us, therefore, that in the case of the experimental lesions of the rabbit, the theory advanced by us is the most satisfactory.

We conclude, then, that mechanical strain with its physico-chemical sequels is responsible for both the cardiac hypertrophy and myocarditic changes in the rabbit's heart.

Let us now briefly consider how far our observations and theoretical considerations are applicable to certain pathologic conditions found in man. Here, also, we find a combination of hypertrophy of the heart muscle and interstitial changes, especially increase in connective tissue in a similar manner as in the experimental lesions of the rabbit. Sometimes, the hypertrophy represents by far the more important change; at other times, the connective tissue increase is quite marked. Accordingly, these conditions are designated as hypertrophy of the heart muscle and as chronic myocarditis. In most cases, a combination seems to be present, and it is doubtful whether a sharp division between these two conditions can be maintained.

The same combination of changes is found in the experimental lesions of the heart of the rabbit. Here are noted, just as in the human heart, certain nodular areas of connective tissue overgrowth, especially at somewhat later stages, at a time when the acute lesions have retrogressed to a great extent. In the rabbit's heart we find this condition as the result of strain. The same holds good, to a great extent, in the case of the human heart. We find these changes in persons in whom the heart has to do excessive work in order to overcome increased resistance as in cases of valvular lesions, arteriosclerosis, kidney lesions. It is also possible that in cases in which, under the influence of bacterial or non-bacterial poisons, apparently a dilatation of the heart is primary, the subsequent hypertrophic and myocarditic changes owe their origin to the increase in work to which such hearts are subject in consequence of the dilatation.

There exist, however, some differences between the conditions found in the rabbit's heart and in hypertrophy and myocarditis in man. In the former, the parenchymatous degenerative changes in the muscle cells are more prominent than in the latter. This difference is, perhaps, due to the acuteness of the change in the heart and to the excessive strain, extending over a brief period only in the rabbit, while in man the strain is more chronic, extending over a long period and is usually less at any given time. In the latter we might, therefore, expect the hypertrophic and interstitial changes to prevail. We have, however, seen that also in the case of the rabbit the degenerative parenchymatous changes disappear relatively rapidly, leaving merely some fibrous bands. We may, therefore, assume that in man degenerative parenchymatous changes which perhaps existed at given times—and such changes are occasionally found in cases of hypertrophy—will heal within a brief period of time, leaving behind fibrous nodular bands.

Some pathologists ascribe the cardiac hypertrophy proper to the increased strain, while they interpret the interstitial changes as invariably due to the malnutrition of the muscle, caused by partial or complete occlusion of the coronary vessels. We have shown that in the case of the rabbit's heart in which changes are found similar to those in the human heart, the occlusion of the coronary vessels cannot be held responsible for the myocarditic changes. There we have a uniform cause leading to both hypertrophy and myocarditis. It seems to us that these facts suggest a similar uniform pathogenesis in many cases in which hypertrophy of the heart and myocarditis are combined in man. This, of course, does not exclude the possibility that in other cases partial occlusion of the coronary vessels is responsible for myocarditic changes, nor does it exclude the possibility that toxic substances may likewise cause myocarditic changes.

We believe that attention ought to be drawn to the similarity existing between the experimental lesions in the rabbit's heart and a large class of lesions found in the human heart, and that a similar pathogenesis may be suggested for both sets of conditions, the cardiac hypertrophy and the myocarditic changes.

DIFFUSE SEPTIC PERITONITIS FROM APPENDICITIS

STATISTICS OF 194 CASES

RUSSELL S. FOWLER, M.D.
BROOKLYN

To November, 1910, there came under my care 194 patients with diffuse septic peritonitis from appendicitis of whom 138 recovered, a recovery percentage of 71, and fifty-six died, a mortality percentage of 29. In this series there were at times as many as fifteen consecutive cases without a death. All patients were operated on except six who were actually moribund. An attempt has been made through a study of the 188 cases with operations to reach some conclusion as to the value of the different methods of treatment in diffuse septic peritonitis following appendicitis. It is interesting to note that in eighty-three cases in which treatment consisted of the administration of fluids by mouth, saline enemas every three or hour hours, with the Fowler position, sixty patients recovered, a recovery percentage of 72.3, and twenty-three patients died, a mortality percentage of 27.7. In a series of thirty-nine patients treated by the elevated head and trunk position, the administration of fluids by mouth and nothing by rectum, thirty patients recovered, a recovery percentage of 76.9, and nine died, a mortality percentage of 23.1. Combining the statistics in these two series we have a series of 112 cases in which the elevated head and trunk position was used and fluids were given by mouth; eighty-three of the patients received enemas and thirty-nine nothing by rectum. Of these patients thirty-two died, showing a recovery percentage of 72. Comparing these three sets of figures it would seem that the administration of fluids by rectum had little if any influence on the after-course.

In fifty-eight cases in which the so-called ideal treatment was employed, that is, the Fowler position, nothing by mouth and Murphy proctoclysis, thirty-nine patients *recovered, a recovery percentage of 65.5, and nineteen* died, a mortality percentage of 34.5. Comparing the cases (in all of which the patients were treated by the elevated head and trunk position) in which nothing was given by mouth and those in which fluids were administered irrespective of what the rectal treatment was, there were seventy-two patients who had nothing by mouth, of whom forty-eight recovered, a recovery percentage of 66⅔, while of 122 patients who were given fluids ninety recovered, a recovery percentage of 73.5.

Statistics, if valuable at all, are only valuable when a large number of cases treated along certain lines are considered. These cases were all cases of diffuse septic peritonitis from appendicitis in which on opening the abdomen there was an immediate spurt of pus under tension, not from a localized abscess, but from a general diffusion of the infected fluid. The patients were sick for variable lengths of time. There is but one certain conclusion that can be drawn from the consideration of these cases, and that is that the mortality is much less than was the case before the elevated head and trunk position was employed. As regards additions to this treatment, such as the withholding of all nourishment by mouth or the giving of saline per rectum, these statistics would seem to show that such additions to the original treatment are immaterial. Yet in spite of this apparently logical conclusion I believe that the ideal treatment, i. e., the Fowler position, the keeping of the *stomach empty by withholding all nourishment, or if* the stomach fills through retroperistalsis, by lavage with siphoning dry of the stomach, and the administration of saline by the Murphy method of proctoclysis, should be carried out in the majority of cases. In addition I would suggest that a culture be taken at each operation and a vaccine be immediately prepared and given. In two cases recently in which this was done both showing infection by colon bacillus the results seemed to be better than in cases not so treated. This, of course, will require further confirmation. It can be stated with certainty, however, that the result does not depend on the treatment, except that the elevated head and trunk posture has proved efficacious, but to a great extent on the virulence of the infection and the period of time it has been at work.

The element of time plays the most important rôle and is the chief reason why statistics vary when apparently the same method of treatment has been carried out, though the virulence of the infection must also be considered.

In this series of 188 cases of operation in which the duration of the attacks was made a matter of record the following table has been compiled showing the recovery percentage in relation to the duration of the attack. The first column of percentages indicates the recovery percentage in all cases up to the end of the period marked in the first column of the table; the second column of percentages shows the recovery percentage for *patients operated on in the period indicated in the first* column of the table, i. e., in the first forty-eight hours, eighty-five patients were operated on, fifteen of these in the first twenty-four-hours period, showing a recovery percentage of over 81, while the omission of these fifteen cases gives a recovery percentage of over 77 for those patients operated on in the second twenty-four hours.

RECOVERY IN CASES CLASSIFIED ACCORDING TO PERIOD OF OPERATION

Period of Operation	Number of Cases	Recovered	Recovery % in All Cases	Recovery % for the Period
24 hours	15	15		100
48 hours	85	69	81+	77+
72 hours	122	96	78+	72+
96 hours	153	117	76+	67+
120 hours	174	126	72+	42+
144 hours	177	128	72+	66+
1 week	181	130	71+	50
8 days	182	131	71+	100
10 days	183	131	71+	0
12 days	184	131	71+	0
2 weeks	187	133	71+	66+
3 weeks	188	133	70+	0

A SOURCE OF ERROR IN THE TEST FOR OCCULT BLOOD IN THE FECES *

WILLIAM A. NEWBOLD, M.D.
Assistant Physician to the Jefferson Medical College Out-Patient Medical Department
PHILADELPHIA

Since the recognition of the frequent occurrence of duodenal and gastric ulceration and the subsequent change in many of our views concerning what was formerly referred to as "gastric" and "intestinal" indigestion, the test for occult blood in the feces is more commonly used and has proved its value in aiding to differentiate various digestive disorders. Owing to the prevailing custom of using either the turpentine-guaic or the peroxid-of-hydrogen-guaic test for the presence of occult blood, it seems of importance to point out any possible and probable source of error in the interpretation of the color reaction as found in the chemical examination for blood in the feces.

It is well known that the ingestion of bloody meat, of iron as a medicine and of certain starchy foods will sometimes give a slight color reaction when testing for occult blood, but I have never read or heard mentioned a source of error that I recently discovered. During the examination of a patient suspected of having a duodenal ulcer, the patient made the statement that he was passing blood by the bowel. There was but slight evidence of any local bowel irritation and little in the patient's history to point to the presence of a duodenal ulcer. A specimen of the feces was obtained and superficially it did appear that there was blood mixed with the stool. The guaic-turpentine test gave a deep blue color, but a microscopic examination of the liquid feces failed to reveal any blood-cells although the deepness of the color reaction in the chemical test indicated a quantity of blood. A careful microscopic examination of the feces revealed the presence of minute portions of material that resembled blood but which proved to be watermelon pulp.

It then occurred to me that the coloring matter of the melon pulp might give the characteristic chemical test for blood and an experiment proved this to be true. It was also found that the expressed juice of the melon gave a similar color reaction but in the latter experiment the color did not prove to be so dark a blue as when the pulp of the melon was used.

As watermelon is so common an article of food during the heated season, there must be many persons, both invalids as well as healthy individuals, who, if their feces were subjected to a chemical test for blood, would give a definite blue-color reaction because of the coloring matter of this fruit.

DEEP PERINEURAL INJECTIONS OF BETA-EUCAIN SOLUTIONS IN SCIATICA

A. J. CAFFREY, M.D.
MILWAUKEE, WIS.

It is not my wish, in reporting these few cases, to claim any originality in the treatment of sciatica with beta-eucain solutions, as a complete report of similar cases has been made by D'Orsay Hecht.[1] Also J. Lange[2] reports marvelous results in eleven cases, and it was his method that I followed as closely as possible in the few cases that I have to report. The technic which was used in the first case reported below was used in all the following cases, so I shall avoid repetition.

CASE 1.—Jan. 10, 1906, I was called to J. D., an Austrian laborer, aged 28; he said he had been suffering from sciatica for about six months. When first seen he was unable to walk; he had been bedridden for two months. I had him removed to Trinity Hospital and, with Dr. Arthur Hoyer, who was then intern, injected 100 c.c. of a solution, made by dissolving 2¼ gr. of beta-eucain in 100 c.c. of normal salt solution. The injection was made—after rendering the parts aseptic—at the gluteal fold, midway between the tuberosity of the ischium and the great trochanter, using a large 50 c.c. syringe and a good, stout needle about 3 inches in length. The needle was passed upward and slightly inward, and on depositing a few drops of the solution the parts became deadened to the pain of the needle on its way to the great sciatic nerve. As the point of the needle reached the nerve there was a distinct shudder or twitch of the leg, indicating that we were in the right path, also there was resistance to the point of the needle as it passed through the outer sheath of the nerve. Then we deposited slowly the contents of the syringe, after which we unscrewed the barrel from the needle and, leaving the needle *in situ*, refilled the barrel, attached it again to the needle and deposited the other 50 c.c.

The result was surprising; the patient, who had been in bed for two months, afraid to move for fear of the excruciating pain accompanying motion, rose from the operating table and walked in a sprightly manner from the fifth floor to the third floor of the hospital. He did not go back to bed again but walked around the ward with the other convalescent patients; but after three days he began to complain of pain in the calf of the leg again. Five days after the first treatment, we repeated the treatment with the same good result. He left the hospital a few days after the last treatment and reported to me twice a week for nearly two months. I have seen him at different intervals since and he has had no return of his sciatica.

I have been able to get only five other patients to submit to the treatment, three of whom were cured, or have had no return of sciatica for a year following the treatment, nor up to the present, as far as I know. The two remaining patients were benefited at the time, but would not submit to a second injection. In all the cases here reported the patients had been suffering from one week to six months.

CASE 2.—Adam M., aged 29, tanner, suffering from sciatica for five weeks; two weeks in bed. Feb. 20, 1907, I injected 100 c.c. of beta-eucain solution 1 to 1,000, into great sciatic nerve. Relief was instantaneous and patient got out of bed the same day; relapse set in about two weeks later. I repeated the treatment with resulting cure.

CASE 3.—W. T., colored waiter, aged 48, March 15, 1908, injected 100 c.c. of the solution, as described, into sciatica nerve. The patient was relieved of the pain instantaneously, but did not have the use of the left leg for about three days. After considerable massage he was able to move around. This case alarmed me for a while, as I thought the patient had developed paralysis after the injection. His pain returned when he recovered the use of his leg. I repeated the treatment and while he complained for a time of being "weak" in the left leg, he had no return of the sciatica. I have seen him a number of times since and he has had no trouble with his legs.

CASE 4.—A. G., aged 42, laborer; lived in a very cold house; slept between two feather beds. I was called to this patient Feb. 20, 1910, and found him with an acute case of sciatica. I used the injection on him Feb. 21, and was obliged to repeat at weekly intervals four times before I got a cure. He would get relief for two or three days, but the pain would return. I also had to resort to the hypodermic several times in this case.

CASE 5.—H. H., brewery hand, aged about 40; called at my office, Nov. 20, 1910, with sciatica of two months' standing. I injected 100 c.c. solution beta-eucain; the patient stated that his pain was relieved instantly. He left the office and I have not seen him since; I do not know if he had any return or not.

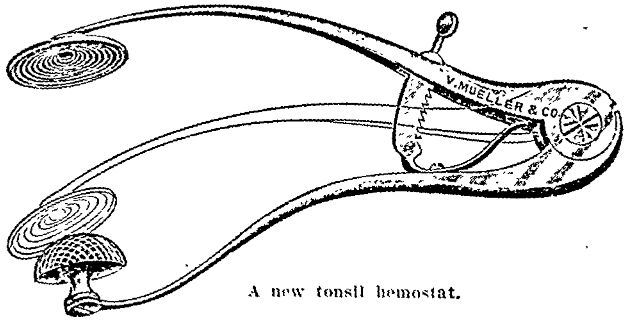
CASE 6.—P. O., laborer, called at the office, March 16, 1911, suffering from sciatica. I used 100 c.c. beta-eucain solution. He obtained some relief, but returned March 21, saying that he was worse than ever. He refused a second injection and asked for medicine. I gave him aspirin and codein, but have not heard of him since.

I believe, with Dr. M. R. Barker, that sciatica is at first a neuralgia, but later becomes a neuritis, with adhesions between the nerve-sheath and the nerve-substance; this brings about a contraction and thickening of the nerve-sheath; so when a large quantity of solution is forced into the nerve there is an expansion of the sheath and a breaking up of the adhesions. In addition, we have the anesthetic effect of the beta-eucain.

A NEW TONSIL HEMOSTAT

A. M. CORWIN, M.D.
CHICAGO

The free hemorrhage that occurs in tonsillectomy under general anesthesia suggests the routine use of mechanical hemostasis, as logically indicated to prevent needless loss of blood in all cases and to secure a nearly bloodless field while the second gland and the adenoid are excised.



A new tonsil hemostat.

The accompanying illustration shows a tonsil hemostat which I have devised and found most satisfactory in every respect after experimenting with several instruments already on the market. This contrivance is best used in pairs, though each instrument is applied on either side of the throat with equal facility. Several layers of gauze are attached to the bulbous extremity of the inner arm; the outside arm carries a disk for counter pressure. The spring ratchet makes adjustment easy for removal or for inserting the instrument, and when both hemostats are in place, excision of the adenoids is not interfered with because the arms are formed to follow the buccal curve. Removal of these instruments one at a time enables the operator to handle any persistent hemorrhage that may follow, by use of long hemostatic forceps for torsion or ligation when needful.

A NEW CONCEPTION OF IMMUNITY

ITS APPLICATION TO THE CULTIVATION OF PROTOZOA AND BACTERIA FROM THE BLOOD AND TO THERAPEUTIC MEASURES *

C. C. BASS, M.D.
Assistant Professor of Tropical Medicine and Clinical Medicine in Tulane University
NEW ORLEANS

Lysis of protoplasm, either protozoal or bacterial, by the body fluids depends on two substances: (1) amboceptor, which is generally specific, but may sometimes be common, and (2) complement, which is common with reference to antigen, but is more or less specific with reference to the source of amboceptor. This complement in man's serum is more active with specific amboceptors in man's serum than with specific amboceptors in the serum of other animals.

When a foreign protoplasmic substance, protozoal or bacterial, is introduced into the tissues of man, specific amboceptors develop and may be demonstrated in the body fluids, especially in the blood-serum. These amboceptors are capable of dissolving large quantities of the same kind of protoplasm in the presence of sufficient complement, but are inactive in the absence of complement. Amboceptors are not destroyed by moderate heat (56 C) or by considerable age.

Complement acts with specific amboceptors to dissolve and destroy large quantities of protoplasm in the presence of specific amboceptors against the particular protoplasm, but it is inactive in the absence of such amboceptors. Human complement capable of acting with human amboceptor to produce lysis, though generally supposed to require at least moderate heat to inactivate or destroy it, as a matter of fact is destroyed by any temperature above normal body temperature (37 C) and with a rapidity depending on the temperature. A temperature at 40 C. (104 F.) destroys the complement in human serum in from fifteen to thirty minutes, and prevents lysis regardless of the amount of amboceptor employed.

Freshly drawn human blood contains little or no complement capable of acting with human amboceptors, but under favorable conditions it develops at a variable rate and in varying quantities depending especially on the temperature at which the blood is kept. The most favorable temperature is considerably below body temperature. No human specific complement develops at ordinary fever heat, 38 to 40 C. (101 to 104 F.), such as obtains locally and often generally in most inflammations. Bacteriolysis or protozoalysis, by far the most important of the known protective processes of the body fluids of man through which the specific infecting organism should be destroyed, is thus prevented by the local or general temperature regardless of the amount of amboceptor present.

In the event that human complement has developed in a blood (which it does under favorable conditions within a few hours), it increases in amount for a time. Then it again disappears in from thirty to seventy-two hours according to various conditions.

When an individual is infected with the malarial plasmodium, *Spirochæta pallida*, the bacillus of typhoid, etc., his blood soon contains large amounts of amboceptor against the infecting organism. If such blood is drawn and employed as a blood-culture in the usual manner and at a temperature at or below 37 C., complement develops within a few hours and acting with the specific amboceptor destroys the organism and prevents successful cultivation. This is the explanation for the many negative typhoid blood-cultures in the latter part of the disease when much amboceptor is present, while cultures in the first few days are generally successful. This may be obviated to some extent by employing special media like bile, which prevents the development of complement. The same result can be obtained by placing the culture immediately at a temperature that will prevent the formation of complement and yet not high enough to destroy the organism. Theoretically and practically, so far as my experiments indicate, blood-cultures will be positive at any time when the organism is present in the blood.

Applying the principles set forth above I have been able to keep alive and to cultivate without difficulty the three common forms of malarial plasmodia—*Plasmodium vivax*, *Plasmodium malariæ* and *Plasmodium falciparum*. They have been repeatedly transplanted successfully. Up to the present writing, cultures have lived in citrated blood for over two weeks. The viability of my cultures has been confirmed by a number of my confrères here.

It is my opinion that the other blood-inhabiting protozoa and bacteria may be grown without difficulty provided these principles are followed and appropriate technic is employed. In the case of malarial plasmodia a special technic, apparently necessary, is that strict anaerobic conditions must be maintained throughout. This, however, is no doubt essential for the satisfactory cultivation of most pathogenic protozoa. Citrated or defibrinated blood is the most successful medium I have found for the cultivation of malarial parasites.

Applying this theory to therapeutic measures we have reversed conditions and we then desire to favor the formation and activity of complement. We may take as a favorable illustration an ordinary infected abscess. As a result of the bacterial toxin, inflammation ensues with its accompanying hyperemia and swelling due to exudation of serum and usually leukocytes. The latter engulf the bacteria but are unable to destroy them for lack of complement, which cannot develop because of the local elevation of temperature.

Finally, sufficient necrosis occurs to give rise to a macroscopic cavity filled with pus. This may continue to increase in amount and the bacteria live and multiply in it. If such pus is withdrawn and some normal serum rich in complement is added it promptly becomes sterile, provided the matter is in sufficiently fine division so that the complement supplied and amboceptor already present in the pus can reach all the bacteria present. If the pus contains some serum that has recently exuded from the tissues and if it is placed at proper temperature, complement develops and can be demonstrated by appropriate test. If on the other hand the pus has been in the cavity many days and at high temperature it will have passed the age at which it can develop complement under any condition. If such old pus is withdrawn and the cavity allowed to refill with new pus fresh from the living tissues, and provided the temperature is kept below the inactivating temperature for human complement, then large amounts of complement develop and the bacteria are destroyed by the combined action of amboceptor and complement. Such new pus withdrawn and kept at appropriate temperature develops an enormous amount of complement—in fact, much more than would an equal amount of blood—probably because of the increased number of leukocytes, the probable source of complement.

---

* Study 3, from the Laboratory of Tropical Medicine and Hygiene, under the direction of Dr. Creighton Wellman, Tulane University of Louisiana.

It should be stated here that complement will develop at quite low temperatures, but that the activity of human amboceptor and complement is much reduced at a temperature of 23 C. (73 F.) or less. Thus the very process it is desired to favor may be materially interfered with by too much cold.

We seem to have herein an explanation for the good derived from cold applications to inflammations, even to the effect of high and incidentally cool climates in tuberculosis of the lungs. The temperature of the diseased foci is lowered by the constant inhalation of cold air.

The possibilities along the lines suggested are so great and the work necessary for the evolution of technic adapted to each of the many problems, both cultural and therapeutic, that will be suggested from time to time and in which this theory plays a part so extensive that one worker will be unable to do any considerable part, and I therefore hope that others will take up this line of experimentation and confirm or contradict the opinions here expressed.

ABSENCE OF APPENDIX

G. FRANKLIN SHIELS, M.D., C.M., F.R.C.S.E.
NEW YORK

History.—Miss X., aged 22, has for the past three years suffered from attacks of nausea after meals with occasional vomiting spells; at times the nausea has existed irrespective of the ingestion of food. Associated with this condition she has had epigastric pain and obstinate constipation. Menstruation has been painful since its inception. She has been treated for the above conditions by several able physicians who have tried all the usual antidyspeptic remedies without avail. Symptoms and signs included slight epigastric pain on deep pressure; distinct pain over the region of the appendix on pressure. A diagnosis of chronic appendicitis with epigastric symptoms and constipation preponderating.

Operation.—Numerous adhesions in the region of the caput cecum were at once encountered, i. e., between the cecum, colon, and right lateral parietal peritoneum; between the small intestine and the large bowel, especially in the region of the ileocecal juncture. These adhesions extended well up the ascending colon; they were freely broken down, necessitating suture of the intestinal peritoneum at several points. The anterior band of the colon was followed to the usual seat of the appendix, but no appendix was found. The case was thought to be one of unusual location of the organ, or of adhesions hiding it; the search was therefore continued in a most sweeping way, the mesocolon was split, and the retrocolonic space searched for a distance of 4 inches above the caput cecum; the ascending colon and the transverse colon were followed as far as the splenic flexure, the sigmoid flexure was examined, and still no sign of an appendix; there were no diverticula; the right tube and ovary were involved in the adhesions. An hour had passed, and since it was felt that the search had been a complete one, the wound was closed.

For years I have taught that the failure to find the appendix was the fault of the operator, and that a careful search, backed by anatomic knowledge and experience, would in all cases discover it. I still hold that, in the very large majority of cases, this is true. I am constrained to admit that, in this case, however, after many hundreds of operations, I have met with an actual case of congenital absence of the appendix vermiformis. During the operation. I had in mind the possibility of the organ being obliterated by former inflammation causing a fibroid degeneration, and its place taken by cicatrical tissue, a condition sometimes called fibrosis; of this there was no evidence. The operation, to date, has relieved the patient of all of her symptoms. This is no doubt due to the relief of the drag of the adhesions caused by an old perityphlitis.

STRANGULATED PEDUNCULATED SUBSEROUS FIBROID COMPLICATING PREGNANCY AT FOUR AND ONE-HALF MONTHS

OPERATION, RECOVERY WITH DELIVERY OF CHILD AT TERM [*]

E. M. LAZARD, M.D.
LOS ANGELES

The coexistence of fibroids of the uterus and pregnancy was formerly considered to be a rarity. By some, the occurrence of fibroids was thought to be an expression of disappointed destiny on the part of the uterus, a morbid activity of a functionally inactive organ. Again, the sterility was looked on as the result of the presence of the fibroids. One author, Carstens,[1] explains the early sterility and late impregnation as being due to a correction of a malposition of the uterus by the developing fibroids, thus allowing conception to take place. The coexistence of these two conditions, fibroids and pregnancy, is not so rare as was formerly supposed, as one finds quite an abundance of these cases reported in the past few years. So, that while functionally inactive uteri may have a greater tendency to fibroid development it would seem that the presence of the fibroid, unless it be of the submucous variety, is not, *per se*, antagonistic to the occurrence of conception. C. P. Noble[2] in an exhaustive article on the complications and degenerations of fibroids with a review of some 7,000 cases, refers to the effect of pregnancy and labor on the tumors, and the possibility of such accidents as "twisted pedicle, necrosis and infection of the tumor," occurring. Mann[3] reports ten cases of pregnancy associated with fibroid and quotes Pinard's report in 1905, of eighty-four fibroids in 13,917 labors and Stratz's report from Schroeder's clinic of 20,000 cases of pregnancy in which there were twelve operated on because of fibroid complication.

In discussing the accidents which might occur in a case of pregnancy and fibroid, Mann says:

> Three conditions must be differentiated: bursting of a pus tube, necrosis of a tumor and twisting of a pedicle. Necrosis generally occurs post abortum or post partum, but occasionally is met with in pregnancy. Twisting of a pedicle of a fibroid is certainly rare and must be extremely so in connection with pregnancy. I have met with two cases of twisting of the pedicle of the fibroid but in neither case was pregnancy possible.

---

3. Mann, M. D.: Fibroid Tumors of the Uterus in Pregnancy, Labor and Puerpéral State, Am. Jour. Obst., June, 1907.

Schauta,[4] in a thorough study of the records of his obstetric and gynecologic clinics from 1891 to 1908, reviews some 111,000 cases in which the coexistence of pregnancy and fibroids occurred in the proportion of seven to ten thousand. In 60 per cent. of the cases of advanced pregnancy, the delivery was normal; in only two cases was interference necessary because of mechanical difficulties. From these various reports and from the fact that the vast majority of cases of pregnancy complicated by fibroids go to term without any accident happening so that they remain unrecognized and unreported, it would appear that the existence of the fibroids is not so inimical to conception as has been supposed. The coexistence of the two conditions, therefore, has ceased to be of interest as a pathologic rarity, but has taken on a very great practical interest from the accidents which may occur in these cases during the course of pregnancy, labor and the puerperal period.

The effect of the presence of the fibroids on the course of pregnancy, once it has occurred, varies with the number, kind and location of the fibroids. Submucous fibroids and deep-seated intramural fibroids by their effect on the endometrium may cause early abortion, placenta prævia or adherent placenta. Noble has reported some cases of tubal pregnancy which were apparently caused by a pressure of a fibroid on the opening of the tube, thus preventing the entrance of the ovum into the uterus. The labor and the puerperal period may be very markedly and deleteriously affected by the presence of the tumor. Fibroids in the lower uterine segment or pedunculated growths from the corpus hanging down into the true pelvis may either so obstruct the entrance to the pelvis as to make the delivery mechanically impossible or cause such a malposition of the presenting part as to make it very difficult. Retention of the placenta and post-partum hemorrhage are also much more common than ordinary, the former because of the changes in the endometrium and the latter because of interference with proper contraction and retraction of the uterine muscle by the presence of the fibroid in the uterine wall. The puerperium may also be complicated by the occurrence of necrosis of the fibroid and sepsis due to the pressure to which the tumor has been subjected during the delivery; this being especially liable to occur in those cases in which forceps delivery has been done. Mumford[5] reports a case of post-partum infection of a fibroid with peritonitis and recovery after hysterectomy.

The effects of the pregnancy on the fibroid are usually the cause of operative interference during pregnancy. These tumors rapidly increase in size during pregnancy, the increase being due to actual growth rather than to edema according to Mann; while Schauta and a number of others ascribe the increase in size rather to the edema. By pressure symptoms, these rapidly growing tumors may demand operative interference before the presence of the pregnancy is suspected.

Quite a number of cases are reported in which operation was performed for multiple fibroids and the pregnancy only discovered at the time of operation. An interesting case is reported by Spaeth,[6] who operated with a diagnosis of torsion of a pedunculated tumor and found an interstitial fibroid which had caused a torsion of the pregnant uterus through 180 degrees, the fibroid which was in the right wall of the uterus being found in the left side of the pelvis. Interstitial tumors may, during the course of pregnancy, be extruded from the uterine wall and become subserous. Submucous tumors may be extruded from the uterus and be the cause of abortion. Gangrene of the tumor during pregnancy is caused either by pressure of the developing uterus on an incarcerated tumor with red degeneration of its substance or by direct interference with its blood-supply by torsion of the pedicle. Taylor[7] reports the case of a patient whom he operated on because of constant and increasing pain and from whom he removed a pedunculated fibroid and two sessile subserous tumors. The pregnancy went on to term with normal delivery. The microscopic report of the pedunculated fibroid showed it to be "a necrotic fibro[illegible]"; that the blood-supply had been [illegible]. He states, however, that there was no torsion of the pedicle so that the changes were probably due to the constant and increasing pressure on the tumor itself.

Torsion of the pedicle of a subserous fibroid during pregnancy seems to be exceedingly rare as stated by Mann. In a careful search of all literature at my command, I can only find the report of three cases of this accident, with a possible fourth. This last one is a reference by McMurty,[8] who says, "Subperitoneal fibromyoma which has become pedunculated has been observed with a twisted pedicle and consequent necrosis, as a result of the increased mobility incident to its ascent from the pelvis to the abdomen." As he does not give the case report, it is impossible to state as to whether it is one of the three, the reports of which I have been able to find. The first two cases are referred to by Olshausen and Veit[9] in their text-book on obstetrics, one of which was Cappie's case in which gangrene of the fibroids led to the death of the patient from peritonitis, and Kleinhans' case in which the tumor was removed during pregnancy and the patient recovered and was delivered at term. The third reported case was that of Barrows[10] who in an article on uterine fibroids complicating pregnancy, describes as his tenth case a pedunculated fibroid, twice the size of a fetal head which had crowded the pregnant uterus down into the pelvis and which had numerous adhesions. He operated with a diagnosis of torsion of an ovarian cyst and removed the fibroid which was becoming gangrenous, the circulation having been shut off by two twists in the pedicle. The patient aborted a fifth-month pregnancy two days after the operation and then had an uninterrupted convalescence.

In view of the extreme rarity of this complication as evidenced by the very few cases reported, among the hundreds of operations for the various accidents in which pregnancy and uterine fibroids coexisted, I thought it would be of interest to report in detail the following case o[illegible] [illegible]rsion of a pedunculated subserous [illegible] a four and a half months' pregnancy.

History.—On the morning of April 15, 1910, I was called to see Mrs. G., who gave the following history: She had had the ordinary diseases of childhood. The year before she had been under a doctor's care for what she said was heart trouble. She said her heart beat too many times. She first menstruated at 13 years of age, was always regular, periods recurring every twenty-four days, the flow was scanty, and she had no pain. There never was any intermenstrual bleeding. She had been married five years. She had never used any preventive measures against conception and had never conceived until this time. Her last period had been about Jan. 1, 1910. Since that time she had had the usual symptoms of a beginning pregnancy. About March 1, 1910, she first noticed a lump in the right lower abdomen which could be moved about rather freely. She consulted her women friends, who assured her it was the baby's head, and that it was all right. I afterward learned that she complained of pain in her right side from the beginning of pregnancy. Before she was aware of her pregnant condition she had consulted a doctor who told her she had a "water ball tumor" which should be removed. April 14, 1910, about 2 o'clock a. m., she got up to urinate and was taken with a sudden, severe, sharp pain in the lower right abdomen, which almost caused her to faint. She had to have her husband help her back to bed. She remained in bed all that day and the pain eased considerably, but the following day it was worse again.

Examination.—The patient was flat in bed, her temperature 98.6, pulse 115 to 120. On examination of the abdomen the pregnant uterus was felt about three fingers' breadth above the symphysis pubis and deflected somewhat to the left side. On the right side of the abdomen, extending from the pubis to McBurney's point was a well-defined mass, which at first felt like a fetal extremity at term; it had a distinct notch in it. The mass was extremely tender, especially at McBurney's point. On account of the extreme tenderness it could not be distinctly outlined from the uterus. On vaginal examination, the cervix was found softened, the os closed, the uterus enlarged to the size of about four and one-half months' pregnancy; Hegar's and Braxton-Hicks' signs could be elicited. High on the right side of the cervix was felt a sharp edge of a mass. Diagnosis was made of a four and one-half months' pregnancy complicated by either an extra-uterine pregnancy, appendicitis, pus tube, ovarian cyst with torsion of the pedicle or a pedunculated fibroid with torsion of pedicle. Patient was sent to the hospital for further observation and probable operation.

April 15, at 5 p. m. temperature was 99.2, pulse 120. The mass in the right lower abdomen was apparently a trifle larger and considerably more painful; the patient was obliged to sit up in bed with legs drawn up to get any relief from pain.

Diagnosis.—Appendicitis was excluded because of definite outline and firm consistency of the mass, of its having been freely movable during first two months of pregnancy and because of a lack of previous symptoms which would indicate appendicular trouble. Pus tube was also excluded because of distinct outline of tumor, its density and previous mobility; extra-uterine pregnancy was also excluded for the same reasons and because of term of pregnancy, four and one-half months, rupture would probably have taken place earlier, besides which normal pregnancy was unquestionably present. Probable diagnosis made of a strangulated pedunculated extra-uterine tumor complicating pregnancy. As to the nature of the tumor, subserous pedunculated fibroid was not considered probable because of absence of previous symptoms of fibroids and because of rarity of these tumors giving trouble of this kind during pregnancy. It was thought that the tumor was an ovarian cyst with a torsion of the pedicle because of previous physical signs and also because of diagnosis of the doctor who saw her two months previously. Operation was urged because of undoubted symptoms of strangulation. Dr. W. W. Richardson was called in consultation and agreed with the diagnosis of extra-uterine tumor and concurred as to the advisability of operation. It was decided to wait until the next day as the family was averse to operative interference. April 16, 1910, condition remained about the same as the previous day, the pain possibly being somewhat increased. The patient and family were again urged as to the necessity of the operation and at their request Dr. E. C. Moore was called in consultation. He agreed with the probable diagnosis of ovarian cyst with torsion of the pedicle. Operation was consented to and was performed at 2 p. m., April 16, 1910.

Operation.—With the patient under anesthesia the tumor mass could be definitely separated from the pregnant uterus. Incision was made in the median line of the abdomen. After opening the abdomen the hand was passed down to the tumor which felt very much of the size and shape and consistency of a kidney. The tumor which had no adhesions and was freely movable in the abdomen was easily delivered out of the wound and found to be a pedunculated, subserous fibroid with torsion of the pedicle. The pedicle was attached to the right lateral wall of the pregnant uterus and was a narrow, long strand of tissue, which was twisted on itself to the size of small twine. The tumor was quite dark in appearance. A catgut suture was passed through and around the pedicle and the tumor was removed. The stump of the pedicle was sewed over with catgut. A small interstitial fibroid about the size of a quarter was found in the anterior wall of the uterus between the tubal insertions. The tumor did not project beyond the surface of the uterus and as it was in a place where it would do no harm during pregnancy and labor and as its removal might cause an abortion, it was not disturbed. The abdomen was closed with a continuous catgut suture of the peritoneum; figure-of-eight silkworm-gut sutures through skin, fascia and muscle; a continuous catgut (No. 2 doubled) approximation of fascia; and a few silkworm-gut approximation sutures of the skin. Time of operation, forty minutes.

May 1, 1910: The convalescence was uneventful, except for a high pulse, 90 to 110, which continued up to the time of her discharge from the hospital. On the fourth day after operation, April 20, the patient felt fetal movements for the first time. The sutures were removed on the tenth day, the wound showing primary union throughout.

Course of Pregnancy and Labor.—The patient was fitted with an abdominal supporter. Throughout the course of pregnancy the patient was very nervous, the pulse remaining constantly from 90 to 100, there was a mitral regurgitant murmur at the apex of the heart, a distinct enlargement of the thyroid gland with other symptoms of hyperthyroidism. The small fibroid increased considerably in size and projected from the surface of the uterus immediately under the cicatrix to such an extent as to be discovered by the patient herself. The cicatrix remained firm but widened somewhat with the advance of pregnancy and became deeply pigmented throughout its course. The urine showed a trace of sugar throughout pregnancy.

Sept. 9, 1910, 6 p. m. the patient started in labor, the second stage beginning about 2 a. m. September 10; at 5 a. m. the pains were recurring about every three minutes and were good uterine contractions. As the patient was very nervous and would not help, the pains were ineffective and there had been no advance for about two hours. Median forceps were applied and a male child delivered without any difficulty. The child was in good condition. Delivery of the placenta occurred one-half hour later and the uterine contraction was good. There was no postpartum hemorrhage. The puerperal period was uneventful. The involution of the uterus was good and at the examination some four weeks after delivery, the small fibroid in the anterior wall of the uterus was not palpable.

611 Lissner Building.

ABSTRACT OF DISCUSSION

Dr. J. S. Baer, Camden, N. J.: I have never had experience with cases of torsion of the pedicle of a fibroid, but I can recall five cases of fibroid tumor complicating pregnancy, and I was especially interested in the conclusion of the paper showing that this tumor had apparently atrophied. In the five cases I speak of there was some difficulty in the delivery. Each case became a forceps case and in each the tumor was not to be distinguished a year afterwards. I want to congratulate Dr. Lazard on the outcome of his case and on the excellence of his report of it. I had another case of fibroid in the posterior wall of the uterus low down in a pregnant woman at term in which a Cesarean section was necessary to deliver the child. I cannot tell anything about the outcome of that tumor because the patient died from pneumonia in about six days, but the child is still living. It has been my experience that all these patients bleed more than usual during delivery.

Therapeutics

ANESTHESIA AND ANESTHETICS

While narcotics have been used from very ancient times, the production of complete unconsciousness for surgical or other procedures is of comparatively recent date.

The properties of many anesthetics, even those now most commonly used, were academically known long before their practical use was demonstrated. Over half a century elapsed between Sir Humphrey Davy's suggestion (1798) that nitrous oxid gas be used to control pain during surgical operations and Horace Wells' demonstration (1844) of its use in dentistry. The exhilarating and anesthetic properties of sulphuric ether were matters of common knowledge long before the public demonstration of their surgical application by Morton and Jackson at the Massachusetts General Hospital in 1846, and even before its tardily recorded use in surgery by Long, of Georgia, in 1842. By 1847 ether was used for surgical anesthetization throughout the civilized world. The anesthetic properties of chloroform, discovered in 1831, seem to have escaped attention until 1847, when J. Y. Simpson, of Edinburgh, used it in operations and introduced it to the profession. Chloroform soon, doubtless on account of its more readily producing anesthesia, more swiftly and with a smaller amount of the drug, became the most generally used anesthetic throughout Europe, and it was used more frequently than ether up to twenty years ago, when ether began to displace chloroform on account of the number of deaths which occurred under chloroform anesthesia.

From the time of the discovery of ether and chloroform, various other preparations and mixtures have been used. Some have been used and recommended; some fell into immediate disuse, while others retained for a shorter or longer time a certain amount of popularity. Nitrous oxid gas, soon after its anesthetic properties were declared by Horace Wells, became more and more popular and more and more generally used for short surgical operations and by all dentists for the extraction of teeth.

With our present knowledge of practical anesthesia, it is not justifiable to depend on any one anesthetic exclusively. The safest anesthetic for a given patient must be decided by the physician in charge, but as a general rule it may be declared that nitrous oxid should be used only for very short operations; that in general ether is a safer anesthetic than chloroform, but that the safety of any anesthetic lies largely with the skill of the anesthetizer. It should also be remembered that some individuals are more shocked by observing even a minor operation under a local anesthetic than they are by the administration of an anesthetic, while with others it may be the reverse. There can be no question that under general anesthesia the surgeon and his assistants are not hurried and undoubtedly do more careful work, especially in preparing and arranging the tissues for the most perfect possible healing. On the other hand, it has now long been demonstrated that even one simple etherization carries with it a certain amount of shock and a certain amount of disturbance, more or less serious, of the internal organs, especially the heart and kidneys. Therefore, repeated anesthetizations, even with ether, are to be deplored, unless such anesthesias are widely separated by time. Also, there is no question that after an anesthesia the patient is in more danger of outside infection as well as from auto-infection, perhaps, from the part that is diseased.

Ether and chloroform seem to produce anesthesia by their action on the central nervous system, somewhat similarly to the action of alcohol. Briefly, they cause a progressive paresis from the highest nerve centers of the brain to the spinal cord centers or reflex centers, to finally the medullary centers, the vital centers. While in general the reflex centers of the genital region and rectum and eye reflexes are the last to become paralyzed in complete anesthesia, it will often be found that the part of the body which is to be operated on, or the part of the body on which the patient had his mind fixed before he was anesthetized, is the part which is the longest sensitive to pain.

It has been asserted that anesthesia is caused by a solution of the fatty constituents of the nerve cells. All fatty solvents seem to be anesthetic if they enter the cell, and the anesthetic power has seemed to be proportional to their ability to dissolve fat. It requires a certain amount of a solvent of the anesthetic in the blood-serum to affect nerve cells in this way, and this varies with the temperature of the animal and of the blood. The concentration of ether in serum necessary for complete anesthesia has been shown to be 1 part to 400, and of chloroform 1 part to 5,000 or 6,000. It has been thought that the rapid recovery which occurs when the anesthetic is removed shows that the fatty constituents are not taken out of the cell, but merely dissolved within it.

Almost all anesthetics are more soluble in lecithin and cholesterin than in water. This is suggested as the reason that the drug accumulates in the nerve cells. As chloroform has a greater ability to combine with lecithin and cholesterin, it thus becomes the stronger anesthetic. By the same action ether and chloroform may combine with the lecithin and cholesterin of the red blood-cells as well as of the nerve cells. This combination with the blood-cell constituents and the nerve constituents also must be very weak; as soon as the ether or chloroform vapor in the lungs is diminished and the anesthetic stopped, the drug immediately begins to excrete from the blood into the alveolar spaces and is exhaled.

AETHER, U. S. P.

Genitive, Aetheris

Description.—Ether $(C_2H_5)_2O$, is a clear, colorless liquid with a specific gravity of about 0.72. It is volatile and inflammable, and, when its vapor is mixed with air, is explosive. It has a sweetish taste and odor.

Local Action.—When it is poured on the skin a sensation of cold is produced by its evaporation, and if this action is produced or hastened, as by an atomizer, the surface may be frozen. If, however, the vapor is prevented from escaping, irritation results, and even vesication may be caused. The vapor of ether is slightly irritant to the conjunctivæ and to mucous membranes.

Systemic Action.—When taken internally it causes transient stimulation of the central nervous system and of the heart. The primary action is not dissimilar to that of alcohol. Its progressive action on the nervous system is to cause paralysis, first of the higher centers, then the spinal cord, and last the medullary centers. Such action, however, is not quite uniform, and it should be remembered that in profound anesthesia the last reflexes to disappear are of the rectum, genital organs and cornea.

The respiratory center is affected both directly and indirectly. At first, owing to the irritation of the mucous membranes of the nose and throat, there is a reflex slowing and occasionally a temporary inhibition of respiration. This may be accompanied by a spasm of the glottis. Such a disturbance need not be caused if the anesthetic is given slowly. Soon, if the anesthesia is forced, or gradually when it is given carefully, the nerves of the throat become numb and the respiration then becomes regular and slower. In other words, the struggling, gasping, and irregular respiration can generally be avoided by the proper administration of the anesthetic. If the operation is prolonged, and with some patients even with a small amount of ether, the respiratory center becomes depressed, the respirations more and more shallow and slower and slower until death may occur by failure of the respiratory center.

Circulation.—The effect on the circulation caused by inhalations of ether is greatly modified by the action of the ether on the respiratory center. In other words, the heart may be very quickly much disturbed, if the respiration is disturbed. If the respiration is regular, the heart is for some time not much disturbed. From irritation of the throat and nostrils the heart may be, at first, reflexly slowed until the irritability of these nerves is dulled. If there is cerebral excitement or nervous excitation the heart becomes more rapid. It also becomes more rapid if there is sudden peripheral dilatation of the arterioles. Soon, however, as the surgical degree of the anesthesia is reached, the heart slows and the pulse becomes full and regular, and remains so throughout the anesthesia, unless a condition of shock occurs. In this condition the surface of the body becomes pale, heat is rapidly lost, more or less vasodilatation and paralysis occurs, the heart becomes rapid and may suddenly fail. In too profound anesthesia, or in insufficient anesthesia when sudden pain may cause pneumogastric inhibition, or in diseased heart conditions, such as chronic myocarditis or when there is disease of the coronary arteries, sudden heart death may occur during ether. Theoretically, however, in normal conditions, ether should give its notice of dangerous paralysis developing by primary impairment of the function of the respiratory center.

In circulatory weakness during anesthesia treatment of the vasomotor paresis is just as important as is the treatment of the weakness of the heart muscle, or even more so.

Throughout the ether anesthesia there is a gradual vasomotor paralysis. The more prolonged the anesthesia, the more the vasomotor weakness. There may be also a slight destruction of red blood-cells. In other words, etherization can never be anything but a circulatory depressant.

The blood-pressure may rise for a short time under ether narcosis, but such a rise is short-lived, and it should be remembered that although with each additional whiff of fresh ether the pulse may improve, the more ether that is administered and the longer it is given, the greater must be and will be the circulatory depression after the anesthesia is over; in other words, the greater the shock.

Pupillary Changes.—The pupils are first dilated under etherization and then contracted, and should remain more or less contracted during narcosis. When the eyelid is raised, if they are slightly dilated, they should quickly contract by light. If they do not so contract, the dilatation of paralysis has occurred, which is a danger signal, indicating that, ordinarily, the anesthesia is too profound.

Alimentary Canal and Respiratory Tract.—The only action on the alimentary canal and respiratory tract when ether is given by inhalation is that of slight irritation. Its irritant action may cause a profuse pouring out of bronchial mucus, and, when swallowed into the stomach mixed with saliva and mucus, it causes nausea and vomiting.

Kidneys.—Ether is always slightly irritant to normal kidneys, and may frequently cause an albuminuria. It is, however, dangerously irritant when there is an acute inflammatory condition of the kidneys, and may cause serious trouble when there is chronic inflammation of the kidneys.

Although the skin generally feels hot during ether anesthesia, the actual temperature falls, doubtless owing to a dilatation of the peripheral blood-vessels, causing not only more or less sweating and therefore a greater evaporation, but also a greater radiation of heat. In other words, heat is lost and the temperature falls during etherization. This makes the heated operating-room a necessity. Also, if the ether vapor is mixed with warm air it is less likely to cause an inflammation of the lungs or a pneumonia.

When ether is administered by inhalation, the absorption takes place mostly from the lungs. On the other hand, while it has been thought that some may be excreted into the stomach, it is probably almost entirely also excreted by the lungs. When ether is taken into the stomach and absorbed there, it also is excreted by the lungs.

Ether anesthetization may profoundly affect metabolism, disturbing the digestive system, increasing the nitrogen output but diminishing normal oxidation. It may cause an increase of the glycogen in the blood, but is not so likely to do so as is chloroform. It may so disturb the liver that bile may be found in the urine, but this also is not so likely as from chloroform. It seems, however, to be a fact that whether anesthesia is produced by ether or chloroform, the ability of the system to protect itself against invasion of germs is diminished for a shorter or longer time. In other words, a patient who has been anesthetized should be surrounded by the most perfect hygiene possible.

Therapy.—Ether is universally used to cause anesthesia, and is generally administered by inhalation. Internally it is sometimes used as a carminative for the same action as would be obtained from a volatile oil. It has been used as a quickly acting cardiac stimulant, taken in one or two whiffs, or administered in water or given hypodermatically; it causes temporary stimulation by its irritant effect. Such use, however, is hardly justifiable, as its secondary effect is always depressant, and as other quick cardiac stimulants are better, such as camphor, ammonia, or even alcohol.

Official Preparations

Spiritus Aetheris, spirit of ether, contains 32.5 per cent. of ether and 67.5 per cent. of alcohol. The dose is 5 c.c. (or 1 fluidram), a teaspoonful, best administered with cracked ice and water. The only object for this preparation is its action as a carminative.

Spiritus Aetheris Compositus, compound spirit of ether (Hoffmann's anodyne) contains 32.5 per cent. of ether, 65 per cent. of alcohol and 2.5 per cent. of ethereal oil. The dose is 5 c.c. (or a fluidram), a teaspoonful, best administered with cracked ice and water. This preparation has no special sedative effects. If alcohol is desired, whisky or brandy should be used.

SATURDAY, NOVEMBER 4, 1911

THE RÔLE OF LIPOIDS IN NUTRITION

The albuminous substances have long had the reputation of standing in unique relation to the activities of living cells. The word "protein" was intentionally selected to designate the preeminent part which these nitrogenous compounds play in the life processes. The eminent physiologist Pflüger coined the expression "protein is the sole living substance" (*nur das Eiweiss ist lebendig*). A recognition of this status has been one of the most effective incentives to those remarkable chemical and biologic studies of the proteins which have been carried out in recent years and have so greatly enlarged our horizon in this direction.

From time to time physiologists have called attention to the possible danger in allowing the supremacy of the proteins to overshadow other essential agencies in successful nutrition. The necessity of supplying a minimum of inorganic compounds—the so-called mineral nutrients—and of furnishing such materials as sodium chlorid, iron and lime salts in suitable amounts and proportions has made itself apparent. In the case of growing individuals the need of iron and calcium has long been recognized; but only of late has the physician acquired a more wholesome appreciation of what the inorganic salts may mean for the preservation of that equilibrium of nutritive processes which we call health. One may recall, as a single illustration, the damage which the undue loss of alkalies from the body, in various conditions of what is broadly termed acidosis, may bring with it.

Again, the other groups of "proximate principles," the fats and carbohydrates, have until quite lately been treated as if they played only an accessory part in nutrition, furnishing energy in interchangeable amounts—merely calorie carriers, as it were. Yet it is more than likely that each of these great groups of nutrients has some specific function in the organism. The appearance of the acetone bodies in the excretions when carbohydrate is withheld is a case in point, leading Rosenfeld to remark that the fats are burned in the flame of the carbohydrates.

Of late, more than passing interest has centered in another group of substances which deserve notice because of their wide-spread distribution in the cells and tissues of both animals and plants. They are termed "lipoids," by which is meant those cell components (other than simple fats) which can be extracted with organic solvents like alcohol and ether. Chemically speaking, they are labile compounds, prone to undergo changes in structure or physical state. The group of lipoids includes various substances, such as the better-known cholesterol and lecithins (phosphatids), members of heterogeneous classes of chemical compounds, though related in some of their characteristic solubilities and physicochemical behaviors. It is not impossible that they exist in the living cell protoplasm in combination with other constituents such as the proteins.

To the lipoids a conspicuous rôle has been ascribed in relation to the phenomena of narcosis, as indicated in the well-known theory of Overton and Hans Meyer.[1] This assumes that the narcotizing substance enters into loose physicochemical combination with the vitally important lipoids of the cell and in so doing changes their normal relation to the other cell constituents, through which an inhibition of the entire cell chemism results. The lipoids have also been associated with various phases of hemolysis and certain branches of immunochemistry.[2] It is by no means evident whether the adult animal organism can manufacture the lipoids, or is dependent on the synthetic capacity of the plant cell to furnish them. An attempt to throw light on this question has lately been made by Stepp.[3] This investigator has fed mice on foods which had been extracted with alcohol and ether to remove all lipoids. He has compared the subsequent duration of life of such animals with that of mice fed with similar unextracted materials or with the same lipoid-free food (usually extracted bread) to which the lipoids have again been added. The experiments show that it is not possible to keep mice alive during long periods when the extracted foods alone are fed, under conditions of environment in which normally fed mice thrive. The question is at once raised as to what specifically essential components of the diet are removed by the methods of extraction employed. They are not inorganic in character: for the addition of the "ash" of the extracts would not restore the nutritive efficiency of the lipoid-free foods. One might question whether a minimum of fat is not necessary for adequate nutrition; but the addition of milk-fat in the form of butter did not suffice to supply the essential missing dietary ingredient. Artificial additions of isolated lecithin and cholesterol were similarly inadequate. In contrast with these negative findings it was observed that the vitally important lipoid substances are present in cream-free milk (*Milch-Plasma*). When the contents of an alcohol-ether extract of separator (skimmed) milk were added to lipoid-free foods the possibilities of uninterrupted health were restored to mice.

[2] For the literature on this topic see Bang: Biochemie der Zelllipoide, Ergebn. d. Physiol., 1907, vi, 131; 1909, viii, 463.

[3] Stepp, W.: Versuche über Fütterung mit lipoidfreier Nahrung, Biochem. Ztschr., 1909, xxii, 452; Verhandl. Kongr. inn. Med., 1911, xxviii, 324; Bedeutung der Lipoide für die Ernährung, Ztschr. f. Biol., 1911, lvii, 135.

There are, obviously, numerous problems to be investigated before the final words in this chapter can be written. We may look forward with interest to further developments in this field to which the American investigators; Koch, Mathews and others, have contributed noteworthy findings. One observation by Stepp is of itself highly significant of what the future experiences may develop. Thus he noted that the lipoid extract from heated milk is not as efficient as that from the unheated. Such facts, evidently related to the instability of the lipoid components, bear directly on the ever recurring controversies of pediatric practice in relation to the pasteurization of milk. For the present, however, the real lesson of the facts cited lies in the warning against the danger of measuring food values solely in terms of calories.

THE CULTIVATION OF THE SPIROCHÆTA PALLIDA

Although the causal relationship between *Spirochæta pallida* and syphilis has been very generally acknowledged almost since the first announcement of the organism by Schaudinn in 1905, this has hitherto been based only on the quite constant association of the parasite with luetic lesions. The lack of definite proof has been due in part to the difficulty of producing the disease in laboratory animals, but mainly to our inability to obtain the spirochete in pure culture. But with the demonstration of the inoculability of rabbits with syphilis, the first of the obstacles was removed, and very recently Noguchi[1] and Hoffmann[2] have independently announced the artificial cultivation of the organisms in purity and with little apparent loss of virulence. Schereschewsky[3] had, it is true, previously succeeded in growing them in artificial media, but he failed to obtain pure cultures, and while other workers were able to accomplish this, their organisms had apparently lost their virulence, and animal inoculations with them failed. Noguchi's method consists in the inoculation of infected tissue from a rabbit into a medium of diluted serum to which a piece of sterile animal tissue had been added. When incubated under strictly anaerobic conditions the spirochetes were found to grow, although at first almost invariably in association with other organisms. Solid media apparently interfered with the growth of the first generations, but with adaptation to artificial conditions this difficulty disappeared. Pure cultures were obtained in several very ingenious ways. In one case the organisms were grown through a Berkefeld filter of suitable porosity, thereby straining off, as it were, the contaminations. Later it was found that in stab agar growths the spirochetes infiltrated a wider zone than did the other bacteria, and inoculations made from this zone yielded pure cultures.

The essential factors for successful cultivation are apparently the presence of sterile fresh animal tissue in the medium, and strict anaerobiosis. The necessity for the latter, however, disappears to some extent with longer cultivation. As is very frequently the case with pronounced parasites, by far the greatest difficulty is presented by the original inoculation of the artificial medium. Injection of the cultures into rabbits is followed after a suitable period by local lesions, in which are found both the anatomic changes characteristic of syphilis, and typical spirochetes in large numbers. Hoffmann's work, which appeared a little later than that of Noguchi, establishes the connection of the disease in the rabbit with that of man even more firmly, inasmuch as his isolation of the organism was directly from the human lesion.

Aside from the demonstration by this work of the specificity of *Spirochæta pallida* as the cause of syphilis, it will probably be of importance in other ways also. For not only does it open up new fields in the study of the etiologic factors of lues, but it contains possibilities in the way of new and more efficient diagnostic aids. And while at present Noguchi's method of cultivation is so difficult as to offer a bar to rapid progress, it is likely that further development of it will result in its simplification.

BENZOATE OF SODA AGAIN

The American public believes that a question is not settled until it is settled right. This probably accounts for the fact that the sodium benzoate question will not down. And yet, although volumes have been written on this much controverted subject, the problem itself is really a simple one. There are three basic facts on which all are agreed: First, no one denies that sodium benzoate in foods may prove harmful in certain quantities, under certain conditions or when given to certain classes of individuals. Second, no one denies that foodstuffs of a high quality can be put up without the use of sodium benzoate; in fact the best food manufacturers do not use this chemical. Third, no one denies that when this chemical is used, scrupulous cleanliness and extreme care in handling are no longer necessary. These are three incontrovertible facts, admitted grudgingly or frankly, as the case may be, by both the pro and anti-benzoate forces. Under the circumstances, then, it is not irrational to conclude that sodium benzoate should not be used as a food preservative.

And now comes from Berlin the "Expert Opinion of the Royal Scientific Deputation for Medical Affairs Regarding the use of Benzoic Acid and its Salts for the Preservation of Food." These experts were requested by the Minister of Education and Medical Affairs in

---

[1] Noguchi: Jour. Exper. Med., 1911, xiv, 99.
[2] Hoffmann: Deutsch. med. Wchnschr., 1911, xxxvii, 1546.
[3] Schereschewsky: Deutsch. med. Wchnschr., 1909, xxxv, 835.

Germany to give their opinion on this subject. In their report, they first describe the chemical and physiologic action of these drugs and then briefly summarize the findings of various scientists on the question at issue. Of the decision of the United States referee board, these German scientists say:

> "The series of experiments in this connection made by the American scientists are of too short duration and the results coupled with certain limitations, so that they cannot be regarded as demonstrating the unconditional non-injurious nature."

After considering all of the evidence on the subject the Scientific Deputation for Medical Affairs reaches the following conclusions:

> "In regard to the admissibility of the use of benzoic acid and its salts for the preservation of food it is mentioned that in France on the basis of a decision of the Commité consultatif d'hygiène publique of October 1, 1888, the Minister of Justice in his circular dated October 16, 1888, prohibited the use of benzoic acid in drinks and food.
>
> "In Austria the Supreme Sanitary Council in an expert opinion dated Dec. 16, 1899, decided in favor of a prohibition of preserving substance containing benzoic acid or its salts, and has adhered to this standpoint in a recent expert opinion and given a detailed justification of the same. In the same sense the Saxon Landes-Medizinal-Kollegium expresses itself.
>
> "The Scientific Deputation for Medical Affairs is likewise of the opinion that the use of benzoic acid and benzoic acid salts for the preservation of food should not be permitted. Even if small doses of the same may be considered harmless for the human organism there is still a danger that, with the addition of these substances to the various food and drinks on the whole quantities would be daily consumed, which would be injurious to the organism. This fear is particularly justified in the case of children, the aged, and weak or sick persons, whereby it is to be observed that even in the case of normal food not preserved with benzoic acid substances are introduced from which benzoic acid comes into existence in the body.
>
> "A further objection against the use of chemical preservatives at all consists in the fact that in its use the food intended for consumption may not be handled with the necessary care and cleanliness to prevent its decay or injury by fungi and that, being neglected by the manufacturers and sellers, under certain circumstances the quality of the goods would suffer. . .
>
> "Similar objections exist regarding albuminous food liable to decay. The experiments of the imperial health office have demonstrated among other things that a slight smell of decay in chopped meat may be concealed, but not entirely removed, by merely stirring or turning over the meat; but on mixing with 0.25 per cent. benzoic acid or sodium benzoate the smell disappears for a time. By this process, therefore, food which has already commenced to decay can be given the appearance of freshness and the purchaser deceived as to its quality."

These findings agree exactly not only with the opinion officially expressed by the American Medical Association in its resolutions on this subject, but also with the opinion held by other scientific bodies and by the intelligent public generally. With the reorganization of the Department of Agriculture, which is as inevitable as it is necessary, it is to be hoped that the United States government will soon cease to hold its present inconsistent position on the subject of the use of sodium benzoate in foods. This chemical has no place in the dietary of any people and certainly its legalized use is a disgrace to an enlightened nation

POLITICS AND THE PUBLIC HEALTH SERVICE

Recent events have drawn attention forcibly to instances of political meddling with the public health service. Within a year the Ohio State Board of Health, long regarded as one of the ablest and most progressive in the United States, has been demoralized by the influence of partisan politics. First eleven members of the laboratory staff were summarily dismissed, including Dr. B. R. Rickards, chief of the laboratory, a well-known scientific worker and for some years past managing editor of the *Journal of the American Public Health Association.* More recently Dr. C. O. Probst, secretary of the Ohio board during a long period, has felt that his duty to the state and his regard for his own honor obliged him to resign his position. Dr. Probst has been a figure of national importance in public health affairs, and it is largely his leadership that has given the Ohio Board of Health its well-deserved reputation in the last decade. An effective health organization has now been swept away. All this is due to the fact that the present governor of Ohio saw fit to fill vacancies on the board with representatives of his own political faith, regardless of merit or especial fitness for the official duties. High political ambitions have been blocked for a lesser cause.

And now, of the three new members appointed by the governor of Massachusetts to the State Board of Health of Massachusetts, not one is an expert or possesses any special qualifications for securing the welfare of the people; but all, of course, are blessed with acceptable political views. It is not necessary to dwell on the absurdity of the assumption that a man's opinion on the tariff or the trusts has any bearing on his fitness to deal with problems of public health. The governor of Massachusetts has likewise exposed himself to criticism by his delay in reappointing Dr. Walcott to the Metropolitan Water and Sewerage Commission. As reported in our news columns last week, a petition bearing the signatures of over two thousand physicians asking for Dr. Walcott's appointment has been presented to the governor. The State Board of Health of Massachusetts has long been one of the most active and efficient in the country. Many men of high scientific eminence have served on its staff, and its scientific work has been given the highest commendation here and abroad. It would be a national misfortune if partisan politics were allowed, even temporarily, to influence its efficiency.

Again, in the State of Illinois, it is true that the State Board of Health has for some years past been the object of much criticism, whether rightly or wrongly we need not here say. Whatever be the facts as to improper licensing, unpleasant rumor and gossip on the subject have been current. The result is that many physicians have not been in sympathy with the Illinois board and as a natural consequence the efficiency of the board has not been high. Loss of confidence, from whatever cause, prevents effective work. It is now stated in the daily press that the governor of Illinois intends to reorganize the State Board of Health with a view to restoring public confidence in the activities of this important body. The new appointments will be watched with interest.

However the problem in these three great states is finally worked out, the duty of physicians is clear. We should insist, in season and out, that expert qualification should be a requisite for any appointment to the public health service or to the ranks of those who have the care of our state and county dependents. The issues are too momentous to allow us to tolerate the injection of partisan politics into public health matters. Intervention in public affairs means for the physician a high degree of self-sacrifice for the common weal, but those who live in a democracy can never forget that eternal vigilance is the price of liberty.

Current Comment

PROTECTING THE HEALTH OF PRISONERS

The frequent occurrence of diphtheria at the New York State Reformatory at Elmira led the superintendent and his medical staff to investigate its source. It was found on taking throat cultures of arriving prisoners that a considerable proportion of them harbored the diphtheria bacillus. When these new prisoners mingled with the healthy reformatory population, epidemics of diphtheria started. An examination of all arrivals since November, 1910, revealed diphtheria bacilli in more than eighty out of 920 prisoners admitted. An isolation hospital had constantly to be maintained. In an effort to eliminate this source of infection, the superintendent obtained an opinion from the attorney-general of the state and instructions from the state commissioner of health which may involve rather far-reaching consequences in relation to the rights of prisoners and the duties of the state and prison authorities regarding the protection of the health of prison inmates. The attorney-general expressed it as his opinion that "the health of prisoners sentenced to reformatories is as much a part of the public health, and they are entitled to as much protection from contagious disease as any other portion of the public," and that it was up to the state board of health to take such steps as were necessary. On this opinion the commissioner of health instructed the superintendent of the reformatory to notify jails or penal institutions that before being sent to the reformatory prisoners must be examined to determine whether or not they are suffering from any infectious or contagious disease. The superintendent accordingly issued such instruction and required that, in addition to a general examination for such diseases, a throat culture must be taken and a certificate of health attached to the commitment. It will be seen that the right is recognized of a prisoner to demand protection of his health either from inmates with whom he is compelled to associate more or less closely, or from insanitary, unhygienic conditions in the prison itself, either from its manner of construction, or from defective care, or from infection of the surroundings by diseased inmates, for which he no doubt might invoke the aid of the courts. It is asserted that many penal institutions, particularly the older ones, are hotbeds of tuberculosis, and that a long term in them means almost certain infection. The possibility of other infections is shown in the instance of diphtheria in the Elmira Reformatory.

BUNCOMBE, BUT NOT BUNCOED

Buncombe County, North Carolina, can boast of the unique distinction of having given an expressive word to the English language. Possibly on account of its name, and because they may have imagined that pseudoscientific buncombe would pass muster there, three enterprising medical fakers opened an office in that county. But they were disappointed. It is true that the local paper accepted as "copy" the buncombe by which these swindlers hoped to gather victims—at regular advertising rates—and it was left to the local medical society to step in and protect the public from the wiles of these impostors. How this was done is described in detail in another place.[1] What the Buncombe County Medical Society did in ridding their locality of undesirable citizens can be done, in the majority of cases, when necessary, in any other county in any other state of the union. It is too bad that work of this sort practically always is left for local physicians to do. No matter how altruistic the motives of physicians may be, the charge will always be made in certain quarters that, in putting medical fakers out of business, the medical profession is not so much concerned with the public's welfare as it is with the elimination of competitors. So long, however, as the newspapers of the country enter into an unholy alliance with medical frauds instead of standing between their readers and these swindlers, so long, probably, will it be necessary for the medical profession to take the initiative in exposing humbugs of this kind.

HAY FEVER AND LOCAL CELLULAR ANAPHYLAXIS

Anaphylaxis at times manifests itself as an exquisitely local process, which is best explained by the assumption that the cells concerned have acquired specifically the power of digesting within themselves the protein which causes the reaction, and hence they are also the chief sufferers from the poisons engendered by this splitting of foreign proteins. An especially striking example is furnished by Bloch and Massini,[2] who found that if a bit of skin from a person infected with trichophyton was transplanted to a healthy person, it would continue sensitive to trichophyton as shown by the local reaction to filtrates from trichophyton cultures. Schittenhelm and Weichardt have described a form of intestinal anaphylaxis which occurs in dogs when they react to a second injection of egg albumin. Violent intestinal symptoms accompanied by a hemorrhagic enteritis extending from stomach to anus, are ascribed to the assumption by the epithelial cells of the task of digesting the foreign protein which reaches them from the blood, with resulting local poisoning by the toxic products of this proteolysis. These authors[3] explain hay fever on the same basis, as a local anaphylactic reaction to pollen proteins. If true, this explains the inefficiency of antipollen serum when injected subcutaneously into hayfever patients, for such an antiserum would be entirely ineffective in combating the local effect of products of proteolysis. The successful treatment of some patients by local application of serum to the nasal mucosa they ascribe to the antiproteolytic power which serums commonly exhibit, whether from normal or from immunized animals. For this purpose, however, normal serum should be as efficient as immune serum, or more so, and there are clinical observations which are entirely in agreement with this idea. Certainly the evidence which is now rapidly accumulating all points towards the anaphylactic nature of hay fever and many related conditions, and from all we know of anaphylaxis there is no hope to be offered of efficient antitoxic serum therapy; but there is every hope that with the progress of our knowledge of anaphylaxis will come the rational therapy of disorders of this class.

---

PENNSYLVANIA'S MEDICAL ORGANIZATION AND THE AUSTIN FLOOD

The town of Austin, Pennsylvania, was destroyed by a flood September 30. There were seven physicians in the town, three of whom were members of the Potter County Medical Society. The secretary of the Pennsylvania State Medical Society advanced $200 for the relief of the physicians, and the board of trustees, which is ex officio a committee on benevolence in that organization, authorized the secretary to receive contributions to assist the physicians of Austin and their families, with the understanding that any money received in excess of what is needed for the present emergency is to become part of the benevolence fund of the state society. Within four weeks, voluntary contributions to the amount of $800 had been received. Can any one doubt that "organization" is effective?

SECTARIAN CATSPAWS FOR FAKERS

In a recent number of the New York *Herald* appeared an account of a meeting held in that city by the National League of Medical Freedom to protest against the establishment of a national department of health. After the usual hysterics regarding the "medical trust" and its awful work, one of the speakers is reported to have said:

> The Owen bill says that the new department of health shall recognize no school of medicine. Why not make it say that it will discriminate against no school of medicine? The bill would say this if Senator Owen was not admittedly the agent of the American Medical Association in this matter.

This is a fair sample of the quibbling and hair-splitting objections raised against this measure. The National League of Medical Freedom, according to its accredited representative, would evidently like the Owen bill better if its wording were amended as indicated. Very well, so far as the American Medical Association has any influence, it will certainly favor such a change, as well as any other changes which will make it clear to the deluded sectarian dupes of the "patent-medicine" interests that the establishment of a national department of health has nothing to do with the individual practice of medicine, and that the passage of the Owen bill will not, in any way, affect the relations between physicians and patients. The wily "patent-medicine" fakers and the food adulterators are trying desperately to make the Eddyites and the medical sectarians believe that they are in danger of martyrdom in the near future. As has been repeatedly stated, the federal Congress has no jurisdiction whatever over the practice of medicine in the states. The followers of cults, fads and sects are needlessly exciting themselves. No one has any desire to interfere with their freedom to believe anything they like. But if a change in verbiage will relieve their overwrought minds and calm their excited fears, it is to be hoped that the suggested change will be made.

Medical News

COLORADO

Personal.—Dr. Leonard W. Ely has retired from the editorship of *Colorado Medicine* and the work has been taken up by Dr. Charles S. Elder, a member of the Publication Committee of the state society.——Dr. Samuel R. McKelvey has succeeded Dr. Benjamin Franklin Wooding as inspector of the Lying-In Hospital of Denver.——Dr. James T. Muir has been elected chief of the Caledonian Society of Colorado Springs.

DISTRICT OF COLUMBIA

Personal.—Dr. W. C. Ruediger has been advanced from assistant professor of educational psychology in the Teachers' College of George Washington University.——Dr. Ralph A. Hamilton has been appointed professor of histology and embryology in the school of medicine of Georgetown University.——Dr. William F. R. Phillips, formerly dean of the medical department of George Washington University, has been elected professor of anatomy in the School of Medicine, University of Alabama, Mobile, and has moved to the latter city.

Society Indorses Wiley.—Resolutions of congratulations to Dr. Harvey W. Wiley were duly adopted by the Medical Society of the District of Columbia at its meeting, October 11. The resolutions set forth that the members have been deeply interested in the investigation of the work of Dr. Harvey W. Wiley in his efforts to secure the enforcement of the pure food regulations; that they heartily rejoice that Dr. Wiley has been completely exonerated from any alleged wrong-doing and that his methods and principles have been fully vindicated, and furthermore present to the President of the United States their commendation of the justice, wisdom and impartiality displayed in his settlement of the dispute.

New Maternity.—The Elisha Francis Riggs Memorial Building of Georgetown University Hospital, especially designed for the care of maternity cases, is under roof and will be in operation in January next. The first floor of the building will provide for twenty-four colored charity patients; the second floor is designed for a similar number of white patients; the third floor will accommodate twenty patients who will pay from $10 to $12 per week, and the fourth floor is to be devoted entirely to private rooms. Each floor has separate delivery and recovery rooms, accommodations for nurses, diet, kitchen, etc.——Another pavilion, 30 by 100 feet, will be erected on the corner of Thirty-Sixth and N Streets, which will be devoted entirely to the care and treatment of mental and nervous diseases. This pavilion will fill a distinct need in the care and treatment of this class of patients and will greatly enhance the facilities for clinical instruction in the University.

---

[3] Schittenhelm and Weichardt: Deutsch. med. Wchnschr., 1911, xxxvii, 867

ILLINOIS

State Health Board Members Resign.—Dr. George W. Webster, Chicago, president; Drs. Henry Richings, Rockford; Perry H. Wessel, Moline, and Walter R. Schussler, Orland, members of the State Board of Health, have resigned.

State Conference of Charities.—At a meeting of the Illinois State Conference of Charities and Correction held in the Illinois Auditorium, Urbana, last week, the following officers were elected: president, Prof. Edward C. Hayes, University of Illinois, Urbana; vice-presidents, F. E. Morey Lyon, Chicago, and Mrs. Nannie Duncan, Bloomington; and secretary-treasurer, Mr. A. L. Bowen, Springfield. The next conference will be held in Springfield.

Personal.—The obituary notice of Dr. Perry H. Wessel, Moline, which appeared in the Chicago *Tribune* of October 29, was exaggerated, as Dr. Wessel is still alive and attending to his practice.——Dr. Ralph T. Hinton, assistant superintendent of the Jacksonville State Hospital has been appointed superintendent of the Elgin State Hospital. Dr. Edward A. Foley, assistant superintendent of the Anna State Hospital, has been transferred to the Jacksonville Hospital. Dr. Charles F. Read, assistant superintendent to the Watertown State Hospital to the Kankakee State Hospital and Dr. Thomas R. Foster, assistant superintendent of the Kankakee State Hospital, to the Anna State Hospital.——Dr. Augustus W. Chandler, Compton, has purchased a residence in North Dixon for $15,000, *which he will remodel and open as a private hospital.*——Dr. John Niess, Jr., Carmi, is reported to be critically ill.——Dr. Sidney D. Wilgus, formerly superintendent of the Elgin State Hospital has been transferred to a similar position in the Kankakee State Hospital and assumed charge of the institution, October 10. On leaving Elgin, October 7, the employees of the State Hospital tendered him a purse containing fourteen $5 gold pieces and a new dollar bill, as a parting gift of remembrance and esteem.——Dr. George J. Schneider, Elgin, fractured his right wrist while cranking his automobile, October 7.——Dr. Henry J. Gahagan, Elgin, fell on the stairs of his office, October 10, and injured his right leg.——Dr. Samuel Nuel Sims, Danville, is said to have been adjudged insane by the Iroquois County Court, October 11, and committed to the Kankakee State Hospital.

Chicago

Baptists Project Hospital.—At the annual meeting of the Illinois Baptist Association, October 18, an appropriation of $100,000 was recommended for the erection of a Baptist Hospital in Chicago.

Hospital Notes.—Pursuant to the wishes of his late wife, James B. Hobbs has presented to the Frances E. Willard National Temperance Hospital a six-flat building on Prairie Avenue, valued at about $25,000.——An emergency hospital is being installed in connection with the temporary police headquarters at Clark and Harrison Streets.

New Hospital Dedicated.—The dedicatory exercises of the new building of the People's Hospital were held October 29-31. On October 29 a mass meeting was held for patrons and friends *on the ground floor of the old building; the Founders' Club* Festival was held the same evening. The evening of October 30 was given over to a banquet to, and inspection of the building by the various contractors and their employees, and on October 31 an informal gathering of members of the medical profession and their families was held. The new building is three stories and a basement in height; of brick, with cut-stone trimmings, fire- and sound-proof, and contains four wards of ten beds each, and twenty-one private rooms in addition to the other necessary accommodations.

INDIANA

Hospital for Elkhart.—Work is to be commenced at once on a modern hospital for Elkhart, and a subscription of $48,000 has been subscribed for this object.

Social Service Department Organized.—Dean Emerson of the Indiana University School of Medicine has organized a social service department in the City Dispensary, Indianapolis.

Employment of School Nurses Not Authorized.—Attorney-General Honan has given an opinion to the State Board of Health that the statute governing medical inspection in schools does not authorize the employment of nurses by the school authorities.

District Society Meeting.—At the annual meeting of the Eleventh Councilor District Medical Society held in Wabash, October 20, Dr. Lorin W. Smith, Wabash, was elected president; Dr. James L. Gilbert, Logansport, secretary and treasurer, and Dr. Godlove G. Eckhardt, Marion, councilor.

Infantile Paralysis.—The epidemic of infantile paralysis, which raged in all parts of the state during the summer and fall, showed a total number of cases of 102 up to October 28. Of these twenty-eight were in cities and seventy-four in the country; three-fourths of all patients are under 5 years of age and seventeen deaths occurred. Dr. William F. King, Columbia City, assistant secretary of the State Board of Health, who makes this report, states that in eighteen instances animals giving evidence of a similar illness, inhabitated the premises.

Communicable Diseases Prevalent.—All the city schools of Madison have been closed and all children have been prohibited from attending public gatherings on account of an epidemic of diphtheria.——The public schools of Petersburg have been closed on account of the prevalence of forty-two cases of scarlet fever.——Diphtheria in epidemic form is reported from Greensburg, where more than forty patients are under quarantine.——The city schools of Crawfordsville have been closed on account of epidemic diphtheria.——From twenty to thirty new cases of diphtheria have lately been reported in Indianapolis each day; Sunday schools have been closed and children have been prohibited from attending public gatherings. The city council has appropriated $3,000 to meet the cost of making 30,000 cultures.

IOWA

Personal.—Dr. Frank S. Hough has opened the Sibley Hospital.——Dr. Phillip G. Young, Hocking, started for Vienna, October 28.——Dr. Charles French, who has been ill with septicemia at St. Luke's Hospital, Cedar Rapids, has been obliged to have the infected finger amputated.

New Hospital Established.—An organization was perfected at a meeting of physicians of Manchester, recently, which assured the establishment of a hospital and nurses' training school in that place. Dr. Harry M. Bradley was elected president of the organization; Dr. Thomas Burns, vice-president; Dr. John A. May, secretary; Dr. Ernest G. Dittmer, treasurer, and Dr. William Coburn, house physician of the new institution. Residence property has been leased as a temporary location, but it is planned later to erect a modern hospital building.

Society Meetings.—At the annual meeting of the Second District Medical Society held in Davenport, October 10, the following officers were elected: president, Dr. Elbridge H. King, Muscatine; vice-presidents, Drs. Edgar B. Henderson, Marengo, and Harry R. Reynolds, Clinton; and secretary-treasurer, Dr. John V. Littig, Davenport (reelected). The next meeting will be held in Davenport, October 19, 1912.——At the annual meeting of the Council Bluffs Medical Society, the following officers were elected: Dr. Matthew E. O'Keefe, president; Dr. Merle F. Warner, vice-president; Dr. David H. Carson, secretary; and Drs. Christian S. Ericksen, Sydney Smith and F. Earl Bellinger, censors.

KANSAS

Hospital Dedicated.—The new hospital of the Medical Department of the University of Kansas, at Rosedale, was dedicated with appropriate ceremonies, October 23.

Personal.—Dr. John D. Horne, Coffeyville, who was recently said to suffer with cerebral hemorrhage, writes that he had simply a second stroke of paralysis, has lost the use of his legs from the hips down, and is confined to his house.——Dr. Romulus Z. Linney, Wichita, is reported to be critically ill, following an operation for appendicitis.——Dr. Byron L. Hale has been appointed city physician of Cherryvale, vice Dr. Benjamin M. Savage.

KENTUCKY

Tuberculin Test Enforced.—At a meeting of the city and county board of health held in Lexington recently, it was decided to begin an enforcement of the State Board of Health regulations for the tuberculin test of cattle. All animals showing a positive reaction will be slaughtered.

State Association Meeting.—The fifty-sixth annual meeting of the Kentucky State Association was held in Paducah. October 24-26, under the presidency of Dr. Joseph E. Wells, Cynthiana. The following officers were elected: president. Dr. David O. Hancock, Henderson; vice-presidents, Drs. Delia Caldwell, Paducah; William L. Mosby, Bardwell, and James R. Steele, Corbin; orator in medicine, Dr. Curran Pope, Louisville; orator in surgery, Dr. Archibald H. Barkley, Lexington; delegates to the American Medical Association, Drs. William W. Richmond, Clinton, and J. W. Ellis, Masonville; councilor for the Fourth District, Dr. Robert C. McChord, Lebanon; and councilor for the Eleventh District, Dr. James S. Lock, Barboursville. The secretary, Dr. Arthur T. McCormack, Bowling Green, and treasurer, Dr. William B. McClure, Lexington, hold over for another year.

Work of the Health Exhibit Car.—The traveling health exhibit car of the Kentucky Association for the Study and Prevention of Tuberculosis, during its recent tour, visited sixty-one towns and cities in ninety-one days and in each of these illustrated lectures were given in halls, churches and schools. During this time 25,039 persons visited the car and inspected the exhibits and 11,565 attended the lectures given. There were distributed from the car 20,144 pieces of literature.

Society Meeting.—At the annual meeting of the Bourbon Medical Society held in Paris, October 17, the following officers were elected: president, Dr. Charles B. Smith, Millersburg; vice-presidents, Drs. Frank Fithian, Paris, and Arthur H. Kelly, Paris; secretary and treasurer, Dr. David B. Anderson, Paris; delegate to the state society, Dr. William Kenney, Paris, and alternate, Dr. John T. Brown, Paris. Resolutions were adopted making suitable recognition of that part of the will of the late Mrs. W. W. Massie, which has made the establishment of a hospital in Paris a possibility.

Personal.—Dr. Louis G. Contri, Milton, is reported to be critically ill with carcinoma of the stomach.——Dr. Evart Hawkins, Finchville, is reported to be seriously ill with ptomain poisoning.——At its annual meeting in Frankfort, October 12, the State Board of Control is said to have entered an order for the removal of Dr. R. L. Willis from the superintendency of the Eastern Kentucky Hospital for the Insane, Lexington.——Dr. W. J. M. Smiser, Skylight, was seriously injured, October 5, by being thrown from his horse.——Dr. David C. Bowen, Elizabethtown, is reported to be critically ill with tuberculosis.——Dr. Everett Layton Pirkey, has been appointed superintendent of the Waverly Hills Sanatorium, vice Dr. Archibald B. Elkin, resigned, to become superintendent of the Elkin-Goldsmith Sanatorium, Atlanta, Ga.——Dr. Frederick A. Stine, Jr., Newport, has been elected a member of the State Board of Health, to succeed himself.

MARYLAND

Charity Conference.—The Seventh Maryland Conference of the Board of Charities and Correction will be held in Baltimore, November 27-29. Among the important matters for discussion is a plan for the establishment of county hospitals for advanced cases of tuberculosis, and the county commissioners will be invited to attend and take part in the conference as a special tax levy will be required to carry out this plan.

Baltimore

Verworn on Narcosis.—Prof. Max Verworn of the University of Bonn, Germany, made an address before the Johns Hopkins Society, October 30, on "Narcosis."

Typhoid Fever.—Many cases of typhoid fever are reported in the city. The Maryland General Hospital reports thirty-five cases; Mercy Hospital, forty; University Hospital, twenty; Franklin Square Hospital, ten; and the Maryland Homeopathic Hospital, three.

Italian Steamer Detained.—As a precaution against members of the crew being infected with cholera, the Baltimore quarantine detained the Italian steamer *Soperga* from the Mediterranean, but no trace of the disease was found on board.

MASSACHUSETTS

Liner Released.—As no cholera infection was found among the crew of the Bucknell steamer *Kioto*, it was released October 6 and allowed to dock at East Boston.

Addition to Dispensary Started.—Work was begun October 5 at the Boston Dispensary, to add a fourth story to the building, which will be arranged as a hospital for infants and children and will accommodate about thirty-five patients.

Large Estate.—The estate of Dr. Charles G. Weld who died in Brookline last June, leaving large bequests to the Massachusetts General Hospital, and the Boston Dispensary and the Boston Lying-In Hospital, has been found to amount to $773,000.

Work of Dispensary.—At the one hundred and seventeenth annual meeting of the Boston Dispensary, the reports showed that more than 30,000 sick poor had been treated during the past year in its clinics, and 10,000 others had been cared for in their homes.

Addition to Consumptives' Home Opened.—On October 8 nearly 7,000 people visited the Free Home for Consumptives, Dorchester, to inspect the addition just completed. This was the first of a series of gatherings for the collection of a fund for opening the addition, which will provide 125 more beds for the institution.

Elections.—At the annual meeting of the Brookfield Medical Club in Ware, October 18, Dr. Ephraim W. Norwood, Spencer, was elected president; Dr. Homer Z. Leach, Gilbertville, vice-president; and Dr. Idelle L. Edmands, North Brookfield, secretary-treasurer.——At the annual meeting of the Attleboro Anti-Tuberculosis Society the following physicians were elected as members of the executive committee: Drs. William O. Hewitt, Frederick V. Murphy, Boston, Clarence W. Estey and George E. McPherson.

Personal. The appointment of Dr. Henry P. Walcott, Cambridge, as a member of the Metropolitan Water and Sewage Commission, was properly confirmed by the council.——Dr. L. Vernon Briggs, Boston, has been appointed a member of the State Board of Insanity.——Dr. Ernest B. Emerson, Tewksbury, formerly superintendent of the North Reading (N. H.) Sanatorium, has been appointed medical director of the State Farm institution, Bridgewater.——Dr. Charles P. Putnam, chairman of the board of trustees of the children's institutions of Boston, has retired.

MISSOURI

Tag-Day.—The total collections of tag-day for Mercy Hospital, Kansas City, amounted to $5,561.

New Building Dedicated.—Governor Hadley, on October 8, presided at the dedicatory exercises of Hadley Hall, the new addition to the State Sanatorium for Incipient Tuberculosis, Mount Vernon. The new building will accommodate about seventy-five patients.

Hospital for Insane Consumptives.—The new building for the care and treatment of insane consumptives at the Fulton State Hospital for the Insane is nearly ready, and will be opened December 1. This is the first hospital of its kind in the state, and has been erected at a cost of about $50,000.

Personal.—Dr. Robert H. Goodier, Hannibal, president of the Missouri State Medical Association, has moved from Hannibal to Stoutsville.——Dr. Harvey S. Reese, Wayland, coroner of Clark County, has resigned and moved to Macon.——Drs. William J. Thompkins, M. O. Bausfield, Ernest J. McCampbell and J. Edward Perry have been appointed assistants to the medical and surgical staff of the Kansas City General Hospital, and will look after the colored patients in the institution.——Dr. Ephraim M. Folsom, Boonville, has returned from Europe.——Dr. James A. Gray, Watson, lost the sight of his left eye from a blow with a baseball recently.——Dr. Samuel A. Johnson, Nevada, has established a sanitarium in Springfield for the treatment of mental and nervous diseases.

Society Meetings.—The Saline County Medical Association held its annual meeting in Marshall, October 20, and elected the following officers: president, Dr. Abner E. Gore, Marshall; vice-presidents, Drs. A. Fletcher Brown, Malta, William L. Sharp, Little Rock, and Frank Aubrey Howard, Slater; and secretary, Dr. John R. Hall, Napton.——The Twelfth Councilor District Medical Association, at its semi-annual meeting, October 10, in Platte City, elected Dr. Eugene C. Robichaux president.—— The Kansas City Academy of Medicine held its annual meeting, October 7, and elected Dr. Samuel S. Glasscock, Kansas City, Kan., president; Dr. Frank C. Neff, vice-president; Dr. Peter T. Bohan, censor; Dr. Charles B. Hardin, treasurer, and Dr. Paul V. Wooley, secretary, all of Kansas City, Mo.

NEBRASKA

State Hospitals for Consumptives.—The state has purchased land at Kearney for the establishment of a city hospital for indigent consumptives and a residence already on the 13-acre tract is to be used as one of the buildings of the institution.

Personal.—Dr. Wright Newman, Aurora, was shot in the face and seriously injured while duck hunting, October 22.——Dr. Anders P. Overgaard, Fremont, was thrown to the pavement of his garage while cranking his automobile, and is suffering from concussion of the brain.

NEW JERSEY

Personal.—Dr. John W. Pratt, Coatesville, Pa., has been elected president of the Medical Society of Chester, Delaware and Montgomery counties.——Dr. E. S. Bloch, Williamstown, has been made medical inspector of the schools of Monroe Township.

Alumni Organize.—At the monthly meeting of the Jersey City hospital staff an alumni association was formed at which Dr. Frank D. Gray, Jersey City, was elected honorary president; Dr. Gustav F. Boehm, Jr., president; Dr. John Lautman, Jersey City, secretary, and Dr. George W. Mueller, Newark, treasurer.

Meeting of Eastern Monmouth Practitioners.—The annual meeting of the Eastern Monmouth Practitioners' Society was held in Red Bank, October 12, and the following officers were elected: president, Dr. D. Edgar Roberts, Keyport; vice-president, Dr. William W. Beveridge, Asbury Park; secretary, Dr. Peter P. Rafferty, Red Bank, and treasurer, Dr. William K. Campbell, Long Branch.

Tri-County Society Meeting.—At the annual meeting of the Tri-County Medical Society of Morris, Sussex and Warren Counties, held in Washington, October 18, the following officers were elected: president, Dr. Abram E. Carpenter, Boonton; vice-presidents, Drs. Enos E. Beatty, Newton, and George W. Cummins, Belvidere; secretary, Dr. Charles B. Smith, Washington, and treasurer, Dr. Frederick W. Flagge, Rockaway.——Dr. Charles S. Heritage, Glassboro, has been elected president and Dr. George S. Redding, secretary, of the Tri-County Medical Society, at the annual meeting held in Bridgeton, October 24. The next meeting will be held in Woodbury.

NEW YORK

Meeting of the State Department of Health.—The Annual Conference of Health Officers met in Carnegie Lyceum, New York City, October 25. The subject discussed was the control of communicable diseases. Dr. Frederick B. Willard of Buffalo called attention to the dangers of contagion from street cars, and urged proper disinfection for trolley cars all over the state. He also urged the enactment of laws prohibiting the dry sweeping of all cars, and thought such a law ought to apply to all public places, whether conducted by the state, municipality or individual.

Sanitary Officers Meet.—The second annual convention of the New York State Sanitary Officers' Association was held in New York City, October 24. Nearly all of the 1,400 sanitary districts in the state were represented at the meeting. A resolution was passed and copies sent to all members of the legislature denouncing the action of the recently adjourned legislature in passing bills appropriating thousands of dollars for the prevention of disease among cattle and hogs, while they cut down the appropriation for the care of human beings suffering from tuberculosis. They also called the attention of the legislature to the need of uniform laws on such matters as the regulation of spitting on sidewalks and in public places, and the lack of uniformity on the treatment of insane patients. The following officers were elected to serve during the ensuing year: president, Dr. Frank Overton, Patchogue; vice-presidents, Dr. Daniel S. Burr, Binghamton; Dr. Louis B. Couch, Nyack, and Dr. Louis H. Brown, Pine Plains; treasurer, Dr. William Stanton, Webster; and secretary, Dr. Montgomery E. Leary, Rochester.

New York City

Harvey Lecture.—Dr. James J. Putnam, Harvard University, delivers the fourth of the present series of lectures at the New York Academy of Medicine on Saturday evening, November 11, at 8:30, on "Freud's Psycho-Analysis."

Plan Two Inebriate Hospitals.—The Board of Inebriety is preparing to build a hospital at Kingston Avenue, Brooklyn, on a site provided by the Department of Charities. A second hospital will be built on Blackwell's Island, where confirmed inebriates will be received.

Money for the Blind.—The Department of Charities recently made its annual distribution of money to worthy blind poor. About $75,000 were distributed, which was much more than ever before, due to the number of blind persons who are learning trades and who before they can earn their own livelihood, are forced to ask for assistance from the department.

Personal.—Dr. Samuel J. Meltzer of the Rockefeller Institute for Medical Research has been elected a member of the Imperial Leopoldina Carolina Academy of Naturalists, at akau.——Dr. Theodore C. Janeway has been appointed a member of the board of scientific directors of the Rockefeller Institute for Medical Research, vice Dr. Christian A. Herter, deceased.

City Increases Appropriations.—The city budget for the coming year provides that the Health Department shall receive $3,392,938, which is an increase of $569,438 over the present appropriation. Bellevue and the Allied Hospitals get an increase of $86,060, and the Department of Charities an increase of $169,155.

Find More Tuberculosis.—The report of Leopold Plaut, president of the United Hebrew Charities, read at the annual meeting of this organization, shows an increase in the number of cases of tuberculosis among working people, the percentage increasing from 14 to 20 per cent. Mr. Plaut said there was no doubt that overwork, congestion and undernourishment were largely responsible for this increase.

Medical College Opened.—Cornell University Medical College opened September 27, with an enrollment smaller than that of the preceding year, which is due to the fact that all matriculants for the degree of M.D. now registered are admitted under the advanced requirements, which necessitated the presentation of a bachelor's degree in science or arts, together with something more than one year's work in physics, chemistry and biology.

Health Department to Take Over Milk Stations.—The twenty-two milk stations of the New York Milk Committee will be taken over by the Health Department on November 1. This action followed an appeal from the Milk Committee to the Health Commissioner to take charge of these stations and the 5,000 babies in the dispensary list of the Milk Committee. The infants will be looked after by department physicians and nurses until the first of the year. The Health Department has been looking after fifteen milk stations, which, together with those of the Milk Committee, will make thirty-seven. It is believed that money will be available to support sixty stations next year.

NORTH CAROLINA

Hookworm Exhibit.—Dr. John A. Ferral, Kenansville, Assistant Secretary of the State Board of Health, had an interesting exhibit at the state fair in Raleigh last week. Hookworm victims were shown, and the parasites themselves with the ova. Physicians were in attendance to examine applicants who desired to be examined for the disease. A lecture with stereopticon views, microscopes and the regular paraphernalia complete of a "hookworm dispensary" in operation were on exhibit. The exhibit attracted much attention, and a large number of examinations of patients were made during the week. Eighteen counties have now made provision for a systematic canvass and examination of all young people through the establishment of hookworm dispensaries.

PENNSYLVANIA

Philadelphia

Personal.—Dr. William Zentmayer has been elected professor of ophthalmology in the Philadelphia Polyclinic and College for Graduates in Medicine, succeeding Dr. Theodore B. Schneideman, resigned.——Dr. Eugene L. Vansant, professor of diseases of throat and nose in the Philadelphia Polyclinic Hospital is recovering from the effects of an infected wound of the right hand.

To Sell Hospital.—Unless the writ is stayed before November 6, the Douglas Memorial Hospital and Training School will be sold by the sheriff to satisfy a mortgage of $25,267. For some time, this institution which recently built a new hospital building, has been in financial difficulties and about a year ago the property was to have been sold at sheriff's sale, but the writ was stayed. Besides the encumbrance of $25,267 on the property there is a mortgage of $31,000.

Increase of Contagious Diseases.—While the health report for the week ending October 28 shows a marked decrease in the total number of deaths as compared with the previous week and also a decrease of more than 10 per cent. in the number of deaths from pneumonia and bronchopneumonia, there were eighty-one new cases of diphtheria reported with eleven deaths. There were thirty-five new cases of chickenpox and one death, and twenty-five new cases of scarlet fever with twenty-five deaths.

Physicians Endorse Cassidy's Work.—At a meeting of the northern branch of the Philadelphia County Medical Society, resolutions were passed endorsing the work of Harry P. Cassidy, special agent of the State Dairy and Food Commission, who is waging a relentless war on the food adulterators, and promising him united and individual support. Prof. Charles H. La Wall, chemist of the commission, was one of the speakers at the meeting and called attention to a list of United States court decisions, just published. In one, a man is fined $200 for adulterating food for cattle, while in another, a firm is fined only $10 for selling putrid ketchup.

UTAH

Personal.—Dr. Edgar G. Bates has been appointed medical examiner of the public schools of Ogden.——Dr. Albert S. Bower, Salt Lake City, was in charge of the emergency staff of physicians at the recent state fair

Utah State Medical Association.—The Utah State Medical Association, at its seventeenth annual meeting, held in Salt Lake City, October 4 and 5, elected the following officers: president, Dr. Robert W. Fisher, Salt Lake City; vice-presidents, Drs. Charles E. West, Salina; Eugene H. Smith, Ogden, and T. H. Howells, Bountiful; secretary, Dr. W. Brown Ewing, Salt Lake City (reelected); treasurer, Dr. Howard P. Kirtley, Salt Lake City, and delegate to the American Medical Association, Dr. Sol G. Kahn, Salt Lake City.

GENERAL

Ohio Valley Meeting.—The thirteenth annual meeting of the Ohio Valley Medical Association will be held in Evansville, November 8 and 9, under the presidency of Dr. William D. Haines, Cincinnati.

Southern Physicians Meet This Month.—The annual meeting of the Southern Medical Association will be held in Hattiesburg, November 14-16.——The Southern Medical College Association will hold its annual meeting in conjunction with that of the Southern Medical Association.

Labor Unions Approve Red Cross Seal.—The National Association for the Study and Prevention of Tuberculosis announces that at the last annual convention of the American Federation of Labor, resolutions were adopted, calling on all members of the federation to endorse the movement for the sale of Red Cross Christmas seals to secure funds for carrying on the campaign against tuberculosis.

Personal.—Surgeon Henry R. Carter, United States Public Health and Marine-Hospital Service, in charge of the United States Marine Hospital, Louisville, is seriously ill with typhoid fever.——Lieutenant Herbert W. Yemans, M.R.C., U. S. Army, has returned to his station, Fort Wayne, Detroit, after attending the Esperanto Congress at Antwerp, Belgium, of which he was appointed temporary chairman. Dr. Yemans was tendered a reception, October 14, at the Randolph Hotel, Detroit.——Dr. and Mrs. Grosbeck Walsh, Cristobal, Canal Zone, started October 9 for their future home in Nicaragua.——The Canadian government has appointed Dr. Gilbert T. Smith, Stamford, Conn., formerly of Baltimore, physician to the American party in the Alaskan boundary survey, to take charge of the medical treatment of the village of Indians at Rampart House, where there is an epidemic of small-pox.

Railway Surgeons Meet.—The tenth annual meeting of the association of Seaboard Air Line Railway Surgeons was held in Washington, October 17-19, and the following officers were elected: chairman of the executive committee, Chief Surgeon Dr. Joseph M. Burke, Petersburg, Va.; president, Dr. Samuel C. Benedict, Athens, Ga.; vice-presidents, Drs. Hampden A. Burke, Petersburg, Va.; Robert L. Harris, Jacksonville, Fla., and John H. Miller, Cross Hill, S. C.; and secretary-treasurer, Dr. Jarrett W. Palmer, Ailey, Ga. (reelected).——The second annual meeting of the Railway Surgical Association of the Southwest was held in El Paso, Tex., October 20 and 21, and the following officers were elected: president, Dr. Francis E. Shine, Bisbee, Ariz.; vice-presidents, Drs. John W. Colbert, Aubuquerque, N. Mex., and Carlos E. Husk, Santa Barbara, Mexico; secretary-treasurer, Dr. Herbert E. Stevenson, El Paso, Tex., and trustees, Drs. Samuel D. Swope, Deming, N. Mex.; H. F. Bailey, Courtland, Ariz., and William L. Brown, El Paso, Tex.

Clinicians to Meet in Philadelphia.—As already announced in THE JOURNAL, the second annual meeting of the Clinical Congress of Surgeons of North America will be held in Philadelphia, November 7-16, with headquarters at the Hotel Bellevue-Stratford. The clinical program is extensive. The first of the evening literary sessions, held in connection with the Philadelphia County Medical Society, will be devoted to the surgery of the upper abdomen; on the second evening the president's address on "Coordination of Undergraduate and Postgraduate Teaching of Clinical Surgery" will be given by Dr. Albert J. Ochsner, Chicago; Dr. Alexis Carrel, New York City, will present a paper, illustrated by lantern slides, on the "Technic and Remote Results of Blood-Vessel Anastomoses," and Dr. William J. Mayo, Rochester, Minn., will give an illustrated address on "Cancer of the Stomach; Its Surgical Cure." The Friday evening session of the congress will be held in conjunction with the meeting of the Philadelphia Neurological Society; the meeting of November 13, with the Academy of Surgery; that of November 14 with the Pediatric Society of Philadelphia, and that of November 15 in connection with the Obstetrical Society of Philadelphia. On the last evening there will also be held a combined meeting of the Section on Otology, Laryngology and Ophthalmology.

American Public Health Association.—The thirty-ninth annual meeting of the American Public Health Association will be held in Havana, Cuba, December 5-9, under the presidency of Dr. Robert M. Simpson, Winnipeg, Man. Dr. M. Varona Suarez is president and Dr. Federico Torralbas, secretary, of the local committee of arrangements. The program of the meeting includes symposiums on Asiatic cholera, hookworm disease and tuberculosis, and papers on pellagra, acute anterior poliomyelitis, typhoid fever, Mexican typhus and isolation hospital construction and management. The laboratory section will consider the reports of the various technical committees on standard methods for the analysis for milk, water and sewage and the bacteriologic diagnosis of tuberculosis, typhoid fever, etc. In the section on vital statistics a symposium will be held on mortality registration in the South and the subject of "Uniform Tables for Statistical Reports and Bulletins" will be considered. The section of municipal health officers will give prominence in its meeting to the promotion of the efficient application of scientific sanitation to municipal conditions. No programs are announced for the new sociological section, or the section on sanitary engineering. The headquarters of the association will be in the Hotel Sevilla, and the general sessions will be held in the rooms of the Ateneo and Circulo de la Habana. The university laboratories will be used for the laboratory section. Ample entertainment has been provided by the courtesy of the people of Havana, including a trip to a tobacco plantation, a banquet at the National Theater, a picnic on the grounds of La Tropical Brewery, a Spanish-Cuban Verbena at the Hotel Sevilla, a trip to Morro Castle, Cabamas, Triscornia Detention Camp and a visit to the wreck of the *Maine*.

Prevention of Infant Mortality.—The second annual meeting of the American Association for Study and Prevention of Infant Mortality will be held in the Hotel La Salle, Chicago, November 16-18. Two popular sessions have been arranged for; two general sessions, and six section meetings. The opening session will be addressed by the president Prof. Charles Richmond Henderson of the University of Chicago, Dr. George B. Young, commissioner of health of Chicago, and Dr. Hastings H. Hart of New York. The speakers at the popular session November 17 will be Dr. Henry J. Gerstenberger of Cleveland, Miss Jane Addams, and Dr. William A. Evans of Chicago, and Dr. Joseph W. Schereschewsky of the U. S. Public Health and Marine-Hospital Service, Washington, D. C. The section meetings will be under the chairmanship of the following: Nursing and Social Work, Miss M. Adelaide Nutting, Department of Nursing and Public Health, Columbia University; Housing, Mr. Lawrence Veiller, secretary and director National Housing Association, New York City; Midwifery, Dr. Mary Sherwood, Baltimore; Eugenics, Prof. H. E. Jordan, University of Virginia; City Milk Supply, Prof. Edwin O. Jordan, University of Chicago; and Continuation Schools of Home Making, Dr. Helen C. Putnam, Providence. Prof. Charles R. Henderson of the University of Chicago is president of the association, and Dr. Cressy L. Wilbur, Bureau of the Census, Washington, is president-elect for 1912. Dr. Frank S. Churchill of Chicago is chairman of the local committee of arrangements; the other members of the committee include Dr. Isaac A. Abt, Mrs. Arthur Aldis, Dr. William A. Evans, Dr. Clifford G. Grulee, Dr. Caroline Hedger, Mr. Sherman C. Kingsley, Mr. Robert Stevenson and Dr. Frank X. Walls. Among the reports to be presented will be one on birth registration, by Dr. Wilmer R. Batt, State Registrar of Vital Statistics, Harrisburg, chairman of the association's committee on that subject.

LONDON LETTER

(From Our Regular Correspondent)

LONDON, Oct. 21, 1911.

Despatch of Another British Commission for the Investigation of Sleeping-Sickness

The British government is sending out a further commission to Central Africa to investigate sleeping-sickness. This will be in charge of Col. Sir David Bruce, assisted by Captain Hamerton of the army medical corps, and Professor Newstead of the Liverpool School of Tropical Medicine. The work will be confined to Nyassaland. An interesting point is that the trypanosome of the disease is believed to be conveyed in this country by a fly other than the tsetse, which is the carrier in other parts of central Africa, for none of this species has yet been found in Nyassaland. The commission, which is going out under the auspices of the Royal Society, is expected to be absent from England for three years. One of its principal objects is to ascertain whether the fly which is supposed to convey the disease depends on the presence of big game. If this is proved to be so it may involve the wholesale destruction of wild animals.

Foundation of a Eugenics Laboratory

An appeal is being made for $75,000 to build a eugenics laboratory in connection with the University of London. As stated in a previous letter (THE JOURNAL, April 8, 1911, p. 1048), Sir Francis Galton left the residue of his estate to the University of London for the endowment of a professorship and laboratory for national eugenics, expressing the wish that the university would see fit "to preserve the capital thereof wholly or almost wholly intact, not encroaching materially on it for cost of building, fittings or library," as the income from his bequest was insufficient to cover both endowment and adequate buildings. In accordance with his suggestion, Prof. Karl Pearson, F.R.S., has been appointed first Galton professor, assisted by a staff of highly trained workers, who now find very insufficient accommodation in a few small rooms temporarily placed at their disposal at University College. The output of the laboratory in the form of original investigations has been very large, and on the ground that the institution has already been of great value and will render increased public service with its fuller development, the University of London feels justified in sanctioning an appeal for such external aid as will enable the staff to carry out effectively this portion of their functions. There can be no doubt that the laboratory has before it plenty of work of important social value. It is now in possession of material received from educational and health authorities in all parts of the country, which alone would require three or four years' labor for the existing staff to analyze and publish, and the bulk of it has direct bearing on the most important social and national problems of the day.

Reform of the Naval Medical Service

In a previous letter (THE JOURNAL, Sept. 23, 1911, p. 1065) considerable reforms in the naval medical service, including the establishment of a new and more modern school at Greenwich, was described. New regulations with regard to the service have now been issued. The limit of age of admission is 28. Every candidate must be interviewed by the director general, who will decide whether such candidate will be allowed to enter for the examination. About thirty commissions will be competed for annually, but the admiralty reserves the power to admit each year six colonial graduates who may be specially recommended by the colonial universities. A successful candidate will be appointed acting-surgeon and is required to pass through a course of six months' study. He will then be reexamined and, if he passes, given a commission as surgeon. His position in the examination determines his seniority. Considerable encouragement is given to candidates to hold house appointments in civil hospitals. Any successful candidate holding or about to hold the office position of resident medical officer is allowed to complete his period of office, and the time so occupied counts for his general service in the navy, though he will not receive pay for it. The course of study during the probationary six months is extensive. In the first two months the acting-surgeon is required to cover the ground of tropical medicine, bacteriology and clinical pathology, hygiene and skiagraphy. This work will be done at the new school at Greenwich. The remainder of the probationary period will be spent at the old naval school at Haslar in learning the routine peculiar to the naval surgeon. If the examination at the end of this course is duly passed, a final one will follow toward the end of the eight years' service. After this each officer will be required to attend a six months' course of postgraduate study and to pass an examination which will qualify him for the rank of staff-surgeon. After eight years' service as staff-surgeon he will be eligible for promotion to fleet-surgeon. The pay of substantive rank has not been altered, but increments of pay are given more frequently than heretofore—every two years. After eight years' service the pay is $5 a day, while staff-surgeons go up to $2,130 a year and fleet-surgeons to $3,340, deputy surgeon-generals to $4,100 and surgeon-generals to $6,500. It must be borne in mind that in addition to the pay the extras and allowances are considerable. A feature which is very likely to attract men to the service is the generous scale of retired pay. After so short a period of service as four years a surgeon may retire with a gratuity of $2,500, and the gratuity is increased by this amount for every additional four years' service up to $10,000, while the pay of retired men who have served from twenty to thirty years varies from $5 to $10 a day.

A Pharmacist Refuses to Supply an Antidote in a Case of Poisoning

An inquest has been held on a clerk who took hydrochloric acid. He was taken to the shop of a pharmacist, who refused to give an antidote. The pharmacist said that it was not his duty to prescribe and that the man should be taken to a hospital. A little chalk and water was asked for and was also refused. Some whiting, obtained elsewhere, was administered. The man was taken to a hospital, where he died. The house-surgeon gave evidence to the effect that if chalk and water had been promptly administered the man's life might have been saved, but admitted that the pharmacist acted within his legal rights in refusing to "prescribe." The jury refrained from expressing any opinion on the subject. The case has not given rise to any comment in the medical or lay press. Of course, the former would in general approve of a pharmacist refusing to prescribe, as one of the stock topics is the grievance of the profession from "counter prescribing" by pharmacists. But surely the pharmacist was wrong in refusing to supply the antidote, and was wanting in both common sense and in humanity. He might have remembered that while it was not his duty as a pharmacist to prescribe, it was his duty as a man to do what he could for a human being in danger of death when medical aid was not available. What would be thought of a layman who saw a person bleeding to death from a wound and refused to try to stop the flow because he was not a surgeon? In this case the refusal was less excusable because the pharmacist possessed technical knowledge which would have enabled him to deal with the case.

The Workmen's Compensation Act

The Workmen's Compensation Act has given rise to some very difficult legal problems. Drawn up in the widest possible manner so as to make the employer liable for any accident "arising out of" the employment, attempts are made to make it cover almost any misfortune which can befall a workman. At Edinburgh, recently, the widow of a gardener, who lived in his own house and had a garden of his own at which he worked, claimed compensation because he died of tetanus. One morning after returning from his master's garden he cleaned his boots without taking them off and in doing this he tore his thumb, under the nail, against a lacing hook in one of the boots. Four days later tetanus began and he died from the disease. There was no evidence to show how the dirt under the nail was obtained but considering the nature of his employment and the fact that the bacillus of tetanus is generally found in manure and leaf-mold, the judge held that it was reasonable to hold that it was obtained when working in his master's garden, but, on the ground that the accident did not arise out of the gardener's employment, he refused compensation. An appeal was made to a higher court where the judge again refused compensation as the man, after leaving his master's premises, was no longer in the latter's employment. He was at liberty to attend to his own affairs, and the accident was not met with in the course of his employment. It had been maintained that the bacillus got into his thumb while he was working in his employer's garden. Even assuming this, it must be shown that it attached itself to his body while he was working for his master. In another case a hatter claimed compensation because he contracted mercurial poisoning while engaged in his trade. The employers maintained that they did not use mercury and that it must have been in the fur which they bought. The judge held that it could not be said that the workman was employed in a mercurial process when the employer did not provide the mercury or even know that it was there.

PARIS LETTER

(From Our Regular Correspondent)

PARIS, Oct. 13, 1911.

The Twenty-Fourth Meeting of the French Surgical Association

The Association française de chirurgie held its twenty-fourth meeting, October 2, under the presidency of Dr. Paul Segond, professor of clinical surgery at the Faculté de médecine de Paris, and surgeon of the hospice de la Salpêtrière. Among those present were many foreign surgeons, notably Arbuthnot Lane of London, Thomson of Edinburgh, E. Laplace of Philadelphia, Charles L. Gibson of New York, W. B. Coley of New York, Sonnenburg of Berlin, Jules Boeckel of Strassburg, Depage of Brussels, Lanz of Amsterdam, Tavel and Girard of Berne, etc.

Dr. Segond read a paper on collaboration between physicians and surgeons. It will be remembered that last year Dr. Delagenière, who then presided, reproached physicians with sending their patients too late to surgeons. His remarks elicited lively protest (The Journal, Nov. 5, 1910, p. 1660). Dr. Segond was more conciliatory. He recognizes that in many circumstances it is very difficult for the surgeon to see clearly without drawing constantly on the more refined means of medical investigation and the special information furnished by the experienced observation and judgment of the physician. In more than one visceral disease the aid of medicine is not only useful and desirable but altogether indispensable. Trepanning, which for many centuries was exclusively surgical, has now become, thanks to its new application, a medico-chirurgical operation *par excellence*. Sometimes it is the appreciation of evident signs which is difficult for the surgeon. Sometimes a uremic patient with headache, vomiting and amaurosis is in danger of being taken to the operating-room as a subject of intracranial neoplasm. There is, therefore, no possible progress in surgical neurology without medical collaboration.

Three subjects were discussed.

DIAGNOSIS AND TREATMENT OF CHRONIC APPENDICITIS

This question continues to hold its interest, judging by the forty-five speakers who enrolled themselves to take part in the discussion. It was necessary to reduce to five minutes the time accorded to each speaker.

According to Dr. J. Silhol, assistant professor at the Ecole de médecine de Marseille, the diagnosis of chronic appendicitis is made especially on the following elements: spontaneous pain which may be aberrant, fixed elicited pain, sometimes deceptive, indefinite digestive symptoms, general symptoms, which are important but not characteristic. Altogether the diagnosis is rather the result of a "special clinical sense" than of a close study of observed symptoms. Dr. Silhol considered, however, that the radioscopic examination was very useful and that it deserved to be systematically employed.

The treatment of chronic appendicitis was the subject of Dr. Charles Walther, surgeon of the hospitals of Paris and *agrégé* professor at the Faculté de médecine de Paris. If operation becomes imperative in cases of general predominating infections with gastric symptoms in which pains are very sharp, etc., the case is quite different from what it is when appendicitis accompanies biliary lithiasis, lesions of the uterine adnexa, movable kidney, etc. Under such circumstances each case deserves exhaustive study, but most frequently the removal of the appendix is to be recommended. As for the technic, Dr. Walther recommends general anesthesia and the incision which causes the least trauma. It is necessary to cover the stump with peritoneum and not confine oneself to excision alone. It is indispensable to make a wide and methodical exploration of the region, for one may have to deal at the same time with several complications in the epiploon of the colon. The after-treatment, which is often neglected, has great importance. It is not to be recommended that patients be allowed to leave their beds early in complicated cases. Feeding should be carefully supervised. The kidneys should be carefully watched during the first days. The emission of the first gases should be facilitated by suppositories and enemas and a purgative on the fourth day. Phlebitis is a complication which must be reckoned with. Cases of evident phlebitis are ordinarily observed in the left leg. Cases of latent phlebitis, which are more frequent, make themselves known by embolisms, generally pulmonary.

Dr. Laplace of Philadelphia insists on the good results given after appendicectomy by the Murphy proctoclysis, which now renders drainage less necessary. Suppuration and gangrene are not the clearest indications for drainage. The cases in which drainage are indicated, on the contrary, are those in which there is no suppuration, but a vivid redness of the intestine. Gauze drainage is often much better than tube drainage. Dr. Sonnenburg of Berlin, in cases in which the disease is hard to diagnose, recommends radiography, which, however, gives results only if the appendix communicates with the intestine, for it is indispensable that the bismuth should penetrate it. He insists on the rôle of pericolitis, while believing that one ought to remove the appendix in the first place, since this operation affords a certain relief to the intestinal lesion. Dr. Richelot of Paris protests against the idea that appendicitis is only a small part of a very complicated condition—a kind of general auto-infection. Dr. Lanz of Amsterdam recommends that too deep palpation be not used whatever the difficulties in diagnosis, for sometimes deep hematomas may be caused by such means. Dr. Girard of Berne remarks that the Rovsing procedure for eliciting pain at the level of the sacrum is unreliable, but it may be perfected by the aid of rectal insufflation.

TREATMENT OF ACUTE PERITONITIS

Dr. Hartmann, professor of operative medicine at the Faculté de médecine de Paris, remarked that for twenty-five years the chief ideas in the treatment of acute peritonitis have undergone a double evolution. Treatment, exclusively medical at first, then became exclusively surgical; the path thereupon was retraced, and treatment with immobility, diet and ice accepted. This treatment, however, is dangerous. It is now established that an acute peritonitis may be cured when once its cause is removed, even though the whole of the infectious material has not been removed. The basis of treatment when an exact diagnosis has been reached (and it must be reached), consists in suppressing the cause of the trouble. When operative treatment is necessary, preparation for the operation should be simplified. Tincture of iodin is sufficient to disinfect the skin. After general anesthesia, incision should be made according to circumstances. Lavage and evisceration should be avoided. The important thing is to drain well.

Dr. Témoin of Bourges in his paper emphasized the importance of the treatment popularized in the United States by the Fowler brothers and Murphy. All the French surgeons who have used Murphy's method have obtained excellent results. When Murphy's irrigations are not well tolerated the intestine may be irrigated by Billington's procedure after appendicostomy or cecostomy. In all this, however, it is necessary to act promptly and swiftly. This is the secret of success.

OPEN TREATMENT OF FRACTURES

The discussion showed that none of the methods of open treatment of recent fractures is absolutely free from danger. As Dr. L. Bérard of Lyons recognized in his paper, surgery of bones is the province of experienced operators who are able to surmount the difficulties found at every step. There are, however, certain contra-indications. If, indeed, old age is not always a reason to abstain from the open treatment, diabetes, albuminuria, badly compensated heart lesions and visceral scleroses are permanent or temporary obstacles. In all recent closed fractures one should always begin by the use of bloodless methods. The period of traumatic shock should be allowed to pass in order to permit the retrocession of muscular hematomas and articular effusions. Nascent infections may thus be avoided. One should then wait eight or ten days, employing the time by making radiographic examinations; thus the number of operations may be reduced. Dr. Tuffier of Paris was an enthusiastic partisan of osteosynthesis, but many other surgeons made important reservations. Dr. Koch of Groningen, Dr. Lucas Championnière of Paris, Dr. Depage of Brussels, etc., considered suturing of the bones a procedure to be employed only in exceptional cases. The perfect anatomic coaptation of the fragments is not at all necessary for the good functioning of a member. It is necessary also to bear in mind that the presence of a foreign body in the bones often produces complications, and after suture there may be delay in bony consolidation.

THE SURGICAL ASSOCIATION AND DR. DOYEN

At the last session of the association there was a significant occurrence. Dr. Doyen took the floor to proclaim the curative action of "mycolysine," a product of his own invention, which he has already declared repeatedly in the daily papers, "is to transform if not to render completely useless all operative technic of the present day." The audience experienced a certain discomfort. Some foreign surgeons expressed their regrets at hearing, on the floor of a scientific organization of as high order as the Association française de chirurgie, journalistic and sensational communications intended for advertising purposes. A resolution was even offered that henceforward no one should advertise pharmaceutical products before the association. Unfortunately the rules of the meeting prevented this resolution being put to the vote.

The Next Congress of the International Surgical Society

The International Society of Surgery, which was founded at Brussels in 1902, and is composed exclusively of surgeons, has just held its third congress, September 26 to 30, at Brussels. The society has broken with tradition. The next meeting, the first one to be held outside of Brussels, will be held in 1914 in New York under the presidency of Dr. Depage of Brussels.

BERLIN LETTER

(From Our Regular Correspondent)

Berlin, Oct. 13, 1911.

Personal

Professor König of Greifswald has been appointed as the successor of Professor Friedrich as director of the surgical clinic at Marburg. Professor Pels-Leusden, for many years first assistant at the surgical clinic at the Charité, has received a call as director of the surgical clinic at Greifswald in place of Professor König.

As successor of von Pirquet, Professor Pfaundler has been nominated to the first place for director of the pediatric clinic at Breslau.

Professor Strasburger of Bonn has been called as successor of the deceased Professor Stern of Breslau. It is scarcely to be expected, however, that he will accept the call.

Medical Inspection of Corpses Before Cremation

According to the directions for the administration of the cremation law an official medical certificate as to the cause of death is required. The necropsy shall be undertaken as soon as possible after death. The official certificate as to the cause of death must give an exact statement as to the manner in which the death was produced. The conduct of the necropsy by artificial light is not permissible, and it should be undertaken by the method most adapted to promote the main purpose of the law, namely, to prevent the concealment of a criminal action by which the death was brought about. By a thorough questioning of the relatives and of the attending physician the medical official shall obtain an exact picture of the course of the disease immediately preceding death and the circumstances under which death resulted.

Tuberculosis Mortality in Prussia in 1910

According to the recently prepared official statistics the tuberculosis mortality in the kingdom of Prussia in the year 1910 has undergone a further reduction. Compared with 1908 the number of deaths was reduced by 2,841 and compared with 1909 by 392. The figures for 1910 are the lowest which have been obtained since 1875, that is, since the establishment of the Prussian statistical bureau. Still even in 1910, 60,479 persons died of tuberculosis in Prussia; 31,090 males and 29,389 females. Of the different ages those between 30 and 40 afford the greatest number, namely, 5,242 men and 5,572 women. The greatest rate reckoned for 100,000 living is shown by the age group from 50 to 60; of these 30.84 men and 16.89 women died. With reference to 100 deaths the greatest number of tuberculosis cases occurred between the ages of 20 to 25 years, that is, 41.69 men and 47.00 women. The relatively marked reduction of tuberculosis mortality in infancy is notable; there were in 1910 reckoned for 100,000 living, 20.92 deaths as opposed to 20.68 in the year 1909 and 26.68 in 1908. The entire number of infants who died of tuberculosis in 1910 amounts to 2,267.

Comparative Experiments with the Roman and German Print and Handwriting

In the active discussion of the advantages of the Roman and German scripts now going on, Professor Groenouw, the Breslau ophthalmologist, has made an interesting contribution. He undertook experiments by which he endeavored to answer the question which of the two scripts is easier to write or read, in order to obtain a more reliable basis than the previous subjective observations and impressions could give. The most varied series of experiments were arranged by which two different texts of a story, one printed in Roman and the other in German type were submitted. From this was shown that in a dictation lasting from three to five minutes, thirty-four German and thirty-nine Roman syllables could be written in a minute, that is, 15 per cent. more with the Roman method. One can write as much in the Roman in seven hours as in the German in eight. The persons experimented on were naturally equally accustomed to both forms of writing; with one exception they, as a rule, employed the German writing. Of the dictation matter written in the German handwriting, Professor Groenouw could read 341 syllables to the minute and of the Roman 358, that is, 5 per cent. more. The difference in reading of printed matter was not so marked: in the mechanical reading of a text, out of nine repeated trials the Roman type was read quicker seven times, from nine to fifty syllables more to the minute, but in two trials the German print was read faster at the rate of about seventeen to thirty-nine syllables per minute. In reading aloud, an average of 344 syllables of the German print were read per minute as compared with 365 of the Roman. In general the Roman script is superior to the German with regard to its legibility but only to a slight extent. That it is quicker to write, depends on the fact that it requires fewer strokes of the pen than the other; the German *a*, he says, requires six while the Roman requires only two. In one minute Groenouw could write this letter eighty-two times in German and 120 times in Roman. That the Roman print is read somewhat faster by some persons than the German is referable to a number of reasons, principally to the fact that certain German letters, particularly the capitals, in spite of their complex character, are not so easy to distinguish from each other and therefore require a somewhat longer time for their recognition.

VIENNA LETTER

(From Our Regular Correspondent)

Vienna, Oct. 10, 1911.

A Dental Clinic for School Children

The efforts of a private society, the Austrian Society for the Care of the Teeth, have resulted in the erection of a model institute in the western part of Vienna, which will form the nucleus of a series of similar clinics. This *Schulzahn-Klinik* is a special small building containing a waiting-room, a surgery, a room for the extraction of teeth, a hall for resting after the operation, and is fitted completely up to date in all respects. It will serve as a dental clinic for the children of five schools, mustering some 4,000 boys and girls, between the ages of 6 and 14. As elementary teaching is compulsory with us, all children must go to school. The examination of the teeth of these youngsters was made during the last two years. Nearly all children in Vienna have thus been seen by several competent dental surgeons, whose reports were the bases which served to justify the action of the above-mentioned society. It has been shown that in the majority of cases there were always carious teeth present; in fact, a child with all teeth healthy was an exception. In the poorer districts, no care at all was given to the mouth and teeth by the parents, while in the wealthier districts the children had their mouths cared for, but not systematically. 28 per cent. of all affected children had one tooth carious, 24 per cent., two teeth, 26 per cent., three teeth, while the remainder had four or more teeth diseased. (No mention is made whether this includes such teeth as had been filled up or stopped, or whether only manifestly diseased teeth were considered.) A collection supported by the medical circles resulted in the provision of funds sufficient for the erection of a clinic, and the services of two able dental surgeons were secured. All children deemed fit by the school teacher will be sent to the clinic to be examined and treated. No fee is paid, but only poor children are treated, while those able to pay are advised to see their regular or another dentist. Within a few years, four more clinics of this type will be completed in Vienna.

Marriages

Frank Pennybacker White Hough, M.D., U. S. N., to Mrs. Helen Stewart Spanton of New York City, at Greenwich, Conn., October 14.

Joseph Taber Johnson, M.D., Washington, D. C., to Mrs. Mary Elizabeth McCann, at New Rochelle, N. Y., October 6.

Ernest P. Magruder, M.D., Washington, D. C., to Miss MacGregor of Edinburgh, Scotland, October 23.

Edwin Dial Watkins, M.D., to Miss Minnie Bowles James, both of Memphis, Tenn., October 31.

Walter M. Kingsbury, M.D., to Miss Mary Elizabeth Lane, both of Malden, Mass., October 10.

Sylvan H. Likes, M.D., Baltimore, to Miss Mamie B. Leopold, at Baltimore, October 18.

Roscoe C. Metzel, M.D., Baltimore, to Miss Daisy L. Hines, at Baltimore, October 19.

Albert Louis Mathieu, M.D., to Miss Beulah Akin, of Carlisle, Ind., October 19.

Dr. Segond read a paper on collaboration between physicians and surgeons. It will be remembered that last year Dr. Delagenière, who then presided, reproached physicians with sending their patients too late to surgeons. His remarks elicited lively protest (The Journal, Nov. 5, 1910, p. 1660). Dr. Segond was more conciliatory. He recognizes that in many circumstances it is very difficult for the surgeon to see clearly without drawing constantly on the more refined means of medical investigation and the special information furnished by the experienced observation and judgment of the physician. In more than one visceral disease the aid of medicine is not only useful and desirable but altogether indispensable. Trepanning, which for many centuries was exclusively surgical, has now become, thanks to its new application, a medico-chirurgical operation *par excellence*. Sometimes it is the appreciation of evident signs which is difficult for the surgeon. Sometimes a uremic patient with headache, vomiting and amaurosis is in danger of being taken to the operating-room as a subject of intracranial neoplasm. There is, therefore, no possible progress in surgical neurology without medical collaboration.

Three subjects were discussed.

DIAGNOSIS AND TREATMENT OF CHRONIC APPENDICITIS

This question continues to hold its interest, judging by the forty-five speakers who enrolled themselves to take part in the discussion. It was necessary to reduce to five minutes the time accorded to each speaker.

According to Dr. J. Silhol, assistant professor at the Ecole de médecine de Marseille, the diagnosis of chronic appendicitis is made especially on the following elements: spontaneous pain which may be aberrant, fixed elicited pain, sometimes deceptive, indefinite digestive symptoms, general symptoms, which are important but not characteristic. Altogether the diagnosis is rather the result of a "special clinical sense" than of a close study of observed symptoms. Dr. Silhol considered, however, that the radioscopic examination was very useful and that it deserved to be systematically employed.

The treatment of chronic appendicitis was the subject of Dr. Charles Walther, surgeon of the hospitals of Paris and *agrégé* professor at the Faculté de médecine de Paris. If operation becomes imperative in cases of general predominating infections with gastric symptoms in which pains are very sharp, etc., the case is quite different from what it is when appendicitis accompanies biliary lithiasis, lesions of the uterine adnexa, movable kidney, etc. Under such circumstances each case deserves exhaustive study, but most frequently the removal of the appendix is to be recommended. As for the technic, Dr. Walther recommends general anesthesia and the incision which causes the least trauma. It is necessary to cover the stump with peritoneum and not confine oneself to excision alone. It is indispensable to make a wide and methodical exploration of the region, for one may have to deal at the same time with several complications in the epiploon of the colon. The after-treatment, which is often neglected, has great importance. It is not to be recommended that patients be allowed to leave their beds early in complicated cases. Feeding should be carefully supervised. The kidneys should be carefully watched during the first days. The emission of the first gases should be facilitated by suppositories and enemas and a purgative on the fourth day. Phlebitis is a complication which must be reckoned with. Cases of evident phlebitis are ordinarily observed in the left leg. Cases of latent phlebitis, which are more frequent, make themselves known by embolisms, generally pulmonary.

Dr. Laplace of Philadelphia insists on the good results given after appendicectomy by the Murphy proctoclysis, which now renders drainage less necessary. Suppuration and gangrene are not the clearest indications for drainage. The cases in which drainage are indicated, on the contrary, are those in which there is no suppuration, but a vivid redness of the intestine. Gauze drainage is often much better than tube drainage. Dr. Sonnenburg of Berlin, in cases in which the disease is hard to diagnose, recommends radiography, which, however, gives results only if the appendix communicates with the intestine, for it is indispensable that the bismuth should penetrate it. He insists on the rôle of pericolitis, while believing that one ought to remove the appendix in the first place, since this operation affords a certain relief to the intestinal lesion. Dr. Richelot of Paris protests against the idea that appendicitis is only a small part of a very complicated condition—a kind of general auto-infection. Dr. Lanz of Amsterdam recommends that too deep palpation be not used whatever the difficulties in diagnosis, for sometimes deep hematomas may be caused by such means. Dr. Girard of Berne remarks that the Rovsing procedure for eliciting pain at the level of the sacrum is unreliable, but it may be perfected by the aid of rectal insufflation.

TREATMENT OF ACUTE PERITONITIS

Dr. Hartmann, professor of operative medicine at the Faculté de médecine de Paris, remarked that for twenty-five years the chief ideas in the treatment of acute peritonitis have undergone a double evolution. Treatment, exclusively medical at first, then became exclusively surgical; the path thereupon was retraced, and treatment with immobility, diet and ice accepted. This treatment, however, is dangerous. It is now established that an acute peritonitis may be cured when once its cause is removed, even though the whole of the infectious material has not been removed. The basis of treatment when an exact diagnosis has been reached (and it must be reached), consists in suppressing the cause of the trouble. Dr. Koch of Groningen, Dr. Lucas Championnière of Paris, Dr. Depage of Brussels, etc., considered suturing of the bones a procedure to be employed only in exceptional cases. The perfect anatomic coaptation of the fragments is not at all necessary for the good functioning of a member. It is necessary also to bear in mind that the presence of a foreign body in the bones often produces complications, and after suture there may be delay in bony consolidation.

THE SURGICAL ASSOCIATION AND DR. DOYEN

At the last session of the association there was a significant occurrence. Dr. Doyen took the floor to proclaim the curative action of "mycolysine," a product of his own invention, which he has already declared repeatedly in the daily papers, "is to transform if not to render completely useless all operative technic of the present day." The audience experienced a certain discomfort. Some foreign surgeons expressed their regrets at hearing, on the floor of a scientific organization of as high order as the Association française de chirurgie, journalistic and sensational communications intended for advertising purposes. A resolution was even offered that henceforward no one should advertise pharmaceutical products before the association. Unfortunately the rules of the meeting prevented this resolution being put to the vote.

The Next Congress of the International Surgical Society

The International Society of Surgery, which was founded at Brussels in 1902, and is composed exclusively of surgeons, has just held its third congress, September 26 to 30, at Brussels. The society has broken with tradition. The next meeting, the first one to be held outside of Brussels, will be held in 1914 in New York under the presidency of Dr. Depage of Brussels.

Oliver J. Gray, M.D. University of Maryland, Baltimore, 1902; a member of the Delaware State Medical Society; died at his home in Wilmington, September 29, from pneumonia, aged 31.

Charles Frederick Patterson, M.D. Dartmouth Medical School, Hanover, N. H., 1896; a member of the American Medical Association; died at his home in Rye, N. H., October 17, aged 44.

William Newton Enochs, M.D. Vanderbilt University, Nashville, Tenn., 1888; for several years physician of Carroll County, Tenn.; died at his home in Huntingdon, October 14, aged 46.

David A. Thompson, M.D. Medical College of Ohio, Cincinnati, 1868; a veteran of the Civil War; died at his home in Elizabethtown, Ind., October 17, from heart disease, aged 67.

Robert Boyd Cabell, M.D. College of Physicians and Surgeons, Keokuk, Ia., 1883; formerly of De Witt, Mo.; died at his home in Dolores, Colo., October 4, aged 64.

Jerome D. Bruce, M.D. Jefferson Medical College, 1856; of Sanford, Fla.; a member of the Florida Medical Association; died in Jacksonville, September 28, aged 75.

John W. Baker, M.D. Memphis (Tenn.) Medical College, 1901; of Prescott, Ark.; died in a hospital in Fort Worth, Tex., June 24, from nephritis, aged 37.

Hal B. Canine, M.D. University of Louisville, 1889; died suddenly at his home in Watertown, N. Y., October 1, from acute gastritis, aged 55.

Esrow B. Crow, M.D. Starling Medical College, Columbus, O., 1865; died at his home in Ridgeway, O., October 12, aged 77.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing, and to Oppose Medical Fraud on the Public and on the Profession

"ELECTRO-RADIO" FAKERS

They Tried to Buncombe Buncombe, But Failed

The following communication, to which reference is made in the editorial department of this issue, shows what may be done by an energetic county medical society to protect the public from frauds. It is sent in by a committee appointed by the Buncombe (N. C.) County Medical Society:

"A group of men calling themselves 'doctors' and going by the names of Whittam, Smith and E. D. Brantley, located in Asheville, N. C., about July 1, 1911. They rented a suite of offices, fitted up with handsome furniture (bought on time), and commenced running a series of highly colored advertisements in both local papers of their offices, equipment and skill. In the 'classified' columns they also advertised for a physician registered in North Carolina.

"By their 'wonderful equipment' and 'astounding skill' they asserted they could cure all diseases without the aid of a surgeon's knife or medicine. Their offices soon became crowded, and it was generally understood that they were extracting large sums of money from their patients for the guaranteed cure of everything from paralysis to a run-down feeling. It furthermore became known that they were giving medicine.

"A committee was appointed by the Buncombe County Medical Society to investigate their merits or demerits. The first few days were fruitless, and by legal authority we were informed that unless we could show that they were giving medicine, they could continue their fraudulent practice under the guise of electricity and radium.

"At this time in the August 19, 1911, issue of The Journal of the American Medical Association there appeared a timely article in the 'Propaganda for Reform' department on 'Mayr's Wonderful Stomach Remedy, Another Fake Gall-Stone Cure.' This seemed to fit some of the cases which they were purporting to cure of gall-stones. After searching around a few days we found a reliable witness, who had received the 'gall-stone treatment,' as described in the above-mentioned article. [The 'treatment' here referred to consists essentially in giving the victim a massive dose of olive oil, followed by a saline. The patient is made to believe that the soapy concretions, that are discharged following this procedure, are gall-stones. —Ed.]

"Warrants were then issued for these 'doctors,' charging them with giving *medicine without a license and doing a* fraudulent practice. It seems that they had been unable to secure a licensed physician. Had they been successful, I doubt if they could have been prosecuted.

"In the process of serving warrants these 'doctors' duped the officer, and, as he returned to headquarters for more information, they hurriedly left their offices and 'skipped' town.' The committee was rewarded, however, as the daily newspapers wrote up the exposure, and there was no attempt on the part of the experts to return. By ridding Asheville, however, they will be thrust on another unsuspecting public, and we hope that by calling attention to this prosecution in The Journal they will be caught and prosecuted elsewhere.

"The newspaper and various creditors secured writs for their equipment, which was found to be the cheapest of electrical appliances, and some of the patients were able to attach a portion of their fat bank account. It is believed that, in a few short weeks, they extracted several thousand dollars from our innocent townspeople.

"*The Buncombe County Medical Society directed that* we send to The Journal of the American Medical Association the above report, hoping that its appearance in the pages of The Journal will apprise other communities.

"The committee suggests that it is high time some legislative action be taken for the protection of the public against the exploiters of fake electrical methods of treatment. It is thought by our legal authority that the making of a diagnosis, giving an opinion, applying electrical treatment and charging a fee really amounts to the practice of medicine, and that it should be in licensed hands.

"We further call the attention of the profession to the fact that most of these advertising electric concerns do, as a matter of fact, give drugs, and it is no wonder that electro-therapeutic methods are in such disrepute with the laity, since any faker can legally use them.

"The committee desires to acknowledge the value of the investigations of fraudulent practices that are now being propagated by The Journal, and to call attention to this specific instance.

"C. V. Reynolds, M.D., Chairman,
"A. W. Calloway, M.D.,
"Eugene B. Glenn, M.D.,
"Committee."

CONVICTIONS UNDER FOOD AND DRUGS ACT *

(Concluded from page 1473)

ROYAL LITHIA WATER

William H. Anderson of Waukesha, Wis., sold another of the so-called lithia waters, which contained an unweighable quantity of lithium. It was labeled as a cure for rheumatism, gout, dropsy, etc. It was very evidently misbranded; a charge to which the defendant pleaded guilty and was fined $25. —[*Notice of Judgment, No. 1032.*]

RADIO-SULPHO CANCER CURE

This impudent fraud, which has already been exposed in The Journal[1] was exploited by one Philip Schuch, Jr., of Denver. He also sold, as an accessory, a nostrum which he called Radio-Sulpho-Brew. Radio-Sulpho was an alleged cancer cure; Radio-Sulpho-Brew a "Blood Purifier." Analyzed by the government chemists, Radio-Sulpho was found to consist of a solution of sulphur and sodium hydroxid in water. In this connection it will be remembered that the Colorado state chemist characterized this malodorous combination as "a bad smell capitalized for a million dollars." Radio-Sulpho-Brew was found to be essentially nothing more than a solution of

Deaths

John S. Beck, M.D. University of Pennsylvania, Philadelphia, 1868; a member of the American Medical Association, president of the Second Councilor District Medical Society of Ohio; a member of the Mississippi Valley Medical Association; physician and chief of staff of the Miami Valley Hospital; president of the Montgomery County Board of U. S. pension examining surgeons; supreme medical director of the Fraternal Censer; a public-spirited practitioner of Dayton, and a leader in all advance measures for health and sanitation and the safeguarding of the health of the community; died at his home in Dayton, October 19, from cerebral hemorrhage, aged 69.

Albert C. Wedge, M.D. Western Reserve University, Cleveland, 1857; a pioneer practitioner of Minnesota; a member and formerly president of the Minnesota State Medical Association and once president of the Albert Lea District Medical Society; a member of the Minnesota House of Representatives in 1870-1871, and state senator in 1879-1880; surgeon of the Third Minnesota Volunteer Infantry during the Civil War; one of the most prominent citizens of Freeborn County, a man of strong character, and yet genial and lovable; died at his home in Albert Lea, October 23, from pneumonia, aged 77.

Hermann Kiefer, M.D. University of Heidelberg, Germany, 1849; a member of the American Medical Association, and American Academy of Medicine; formerly United States Consul at Stettin, Germany; formerly city physician at Detroit, and president of the Detroit German Clinic; a regent of, and professor emeritus of practice of medicine in the University of Michigan, Ann Arbor; died in Detroit, October 11, three days after a surgical operation, aged 86.

Thomas Crain Evans, M.D. Hospital College of Medicine, Louisville, 1884; former dean and professor of ophthalmology, otology and laryngology of the medical department of Kentucky University, and of the merged medical schools the University of Louisville; a specialist on diseases of the eye, ear, nose and throat; an excellent organizer and a most lovable character; died at his home in Louisville, October 26, from chronic interstitial nephritis, aged 50.

Rufus Dodd Mason, M.D. State University of Iowa, Iowa City, 1887; a member of the American Medical Association, American Proctologic Society and Medical Society of the Missouri Valley; professor of rectal and pelvic surgery in the John A. Creighton Medical College, Omaha; surgeon to St. Joseph's Hospital, Omaha, and consulting surgeon to Mercy Hospital, Council Bluffs, Ia.; died at his home in Omaha, October 18, aged 51.

Benjamin N. Baker, M.D. Pennsylvania Medical College, Gettysburg, 1856; a member of the American Medical Association; a veteran of the Civil War and one of the oldest practitioners in Dutchess County, N. Y.; assistant surgeon of the First New Jersey Volunteer Cavalry and surgeon of the Twenty-Sixth New Jersey Volunteer Infantry during the Civil War; died at his home in Rhinebeck, N. Y., October 19, aged 78.

Louis Harvey Jones, M.D. Tulane University, New Orleans, 1887; a member of the American Medical Association; formerly a resident of Atlanta, and a member of the board of health; professor of chemistry and medical jurisprudence in the Atlanta College of Physicians and Surgeons from 1890 to 1908; formerly secretary and treasurer of the Medical Society of Georgia; died at his home in St. Petersburg, Fla., October 9, aged 53.

Daniel Webster Crouse, M.D. Long Island College Hospital, Brooklyn, 1869; a member of the American Medical Association and a member of the Judicial Council in 1894 and 1897; formerly president of the Iowa State Medical Society; for thirty-seven years a practitioner of Waterloo, and district surgeon of the Rock Island and Illinois Central systems; died in Citronelle, Ala., October 11, from tuberculosis, aged 66.

Robert L. Burrage, M.D. Bellevue Hospital Medical College, New York City, 1878; for twenty-one years a member of the medical staff of the Prudential Insurance Company and for a long time its medical director; who held a conspicuous position among life insurance specialists; died at his home in Orange, N. J., October 29, from valvular heart disease, aged 53.

Elisha Hopkins, M.D. Harvard Medical School, 1854; for more than half a century a practitioner of Searsport, Me., assistant surgeon of the Fourth Maine Volunteer Infantry, and Surgeon of the Fourteenth Maine Volunteer Infantry during the Civil War; died at his home, October 5, aged 82.

Allen George Rennison, M.D. National Medical University, Chicago, 1896; a member of the American Medical Association, and China Medical Missionary Society; medical director of Mapleview Sanitarium; while making a professional call near Sumner, Ia., October 6, was struck by a train and sustained injuries from which he died a few hours later, aged 41.

Henry P. Merriman, M.D. Chicago Medical College, 1865; a member of the Illinois State Medical Society, Chicago Gynecological Society and Chicago Physician's Club; at one time a member of the faculty of Rush Medical College; for forty years a practitioner of Chicago; died at his home in Santa Barbara, Cal., October 18, aged 73.

Charles Herman Mueller, Jr., M.D. Medical College of Ohio, Cincinnati, 1902; of Hyde Park, Cincinnati; aged 33; died at the home of his father in Cincinnati, October 11, from the effects of a bullet wound of the heart, believed to have been self-inflicted with suicidal intent while despondent on account of the ill health of his wife.

James Gass, M.D. College of Physicians and Surgeons, Baltimore, 1891; a member of the American Medical Association; and local surgeon of the Pennsylvania System at Sheffield, Pa., while driving his automobile over a grade crossing at Stoneham, October 22, was struck by a locomotive and instantly killed, aged 48.

George Malvern Ridgway, M.D. University of Pennsylvania, Philadelphia, 1899; of Trenton, N. J.; a member of the American Medical Association; pathologist to Mercer Hospital, and a specialist in diseases of the ear, nose and throat; died at the Eastern General Hospital, Bangor, Me., October 8, from nephritis, aged 37.

Adoniram Judson Matthews, M.D. Medical College of Georgia, Augusta, 1859; a member of the Medical Association of Georgia; surgeon in the Confederate service during the Civil War; local surgeon of the Southern Railway; died at his home in Elberton, February 5, from carcinoma of the face and throat, aged 76.

Julia Hibben Flagg, M.D. Medical College of Indiana, Indianapolis, 1890; a member of the Washington State Medical Association; attending physician to St. Joseph's Hospital, Vancouver; died at her home in that city, June 3, from injuries received in an accident in which she was thrown from a buggy, aged 46.

Anthony Miller, M.D. University of Louisville, 1879; a member of the Mississippi State Medical Association; a member of the board of trustees of the Mississippi Charity Hospital for several years; recently elected senator from Sharkey County; died suddenly at his home in Rolling Fork, October 7, aged 56.

Carl Crisand, M.D. New York Homeopathic Medical College, New York City, 1884; surgeon to the Worcester (Mass.) Hahnemann Hospital and president of the Worcester Oratorio Society; died at the home of Dr. J. E. Willis in that city, September 30, from cerebral hemorrhage, aged 53.

Albert J. Franklin, M.D. College of Physicians and Surgeons, Keokuk, Ia., 1876; a member of the American Medical Association; a pioneer practitioner and for several terms coroner of Faribault County, Minn.; died at his home in Blue Earth, October 9, from cerebral hemorrhage, aged 69.

Lee Smith, M.D. Rush Medical College, 1856; for many years a member of the American Medical Association and for more than half a century an honored practitioner of Bloomington, Ill., one of the old-time family physicians; died at his home in Bloomington, October 16, aged 79.

Jansen Beemer Mattison, M.D. Bellevue Hospital Medical College, 1867; formerly a member of the Association for the Cure of Inebriety and the New York Academy of Medicine and medical director of the Brooklyn Home for Habitués of Opium, Chloral and Cocain; died September 26.

George Holman Snead, M.D. University of Virginia, Charlottesville, 1855; a member of the Board of Conscripts in the Confederate service during the Civil War; who, after several years of practice, became a clergyman; died at his home in Fork Union, Va., July 1, aged 79.

John A. Osborne, M.D. Medical College of Indiana, Indianapolis, 1879; a member of the Indiana State Medical Association; of Pittsboro; died at the Deaconess Hospital, Indianapolis, March 1, after an operation on the prostate gland, aged 69.

James Burke, M.D. Rush Medical College, 1887; of Gillett, formerly of Manitowoc, Wis.; a member of the American Medical Association; died at his old home in Wayside, Wis., October 12, from spinal disease, aged 55.

Oliver J. Gray, M.D. University of Maryland, Baltimore, 1902; a member of the Delaware State Medical Society; died at his home in Wilmington, September 29, from pneumonia, aged 31.

Charles Frederick Patterson, M.D. Dartmouth Medical School, Hanover, N. H., 1896; a member of the American Medical Association; died at his home in Rye, N. H., October 17, aged 44.

William Newton Enochs, M.D. Vanderbilt University, Nashville, Tenn., 1888; for several years physician of Carroll County, Tenn.; died at his home in Huntingdon, October 14, aged 46.

David A. Thompson, M.D. Medical College of Ohio, Cincinnati, 1868; a veteran of the Civil War; died at his home in Elizabethtown, Ind., October 17, from heart disease, aged 67.

Robert Boyd Cabell, M.D. College of Physicians and Surgeons, Keokuk, Ia., 1883; formerly of De Witt, Mo.; died at his home in Dolores, Colo., October 4, aged 64.

Jerome D. Bruce, M.D. Jefferson Medical College, 1856; of Sanford, Fla.; a member of the Florida Medical Association; died in Jacksonville, September 28, aged 75.

John W. Baker, M.D. Memphis (Tenn.) Medical College, 1901; of Prescott, Ark.; died in a hospital in Fort Worth, Tex., June 24, from nephritis, aged 37.

Hal B. Canine, M.D. University of Louisville, 1889; died suddenly at his home in Watertown, N. Y., October 1, from acute gastritis, aged 55.

Esrow B. Crow, M.D. Starling Medical College, Columbus, O., 1865; died at his home in Ridgeway, O., October 12, aged 77.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING, AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

"ELECTRO-RADIO" FAKERS

They Tried to Buncombe Buncombe, But Failed

The following communication, to which reference is made in the editorial department of this issue, shows what may be done by an energetic county medical society to protect the public from frauds. It is sent in by a committee appointed by the Buncombe (N. C.) County Medical Society:

"A group of men calling themselves 'doctors' and going by the names of Whittam, Smith and E. D. Brantley, located in Asheville, N. C., about July 1, 1911. They rented a suite of offices, fitted up with handsome furniture (bought on time), and commenced running a series of highly colored advertisements in both local papers of their offices, equipment and skill. In the 'classified' columns they also advertised for a physician registered in North Carolina.

"By their 'wonderful equipment' and 'astounding skill' they asserted they could cure all diseases without the aid of a surgeon's knife or medicine. Their offices soon became crowded, and it was generally understood that they were extracting large sums of money from their patients for the guaranteed cure of everything from paralysis to a run-down feeling. It furthermore became known that they were giving medicine.

"A committee was appointed by the Buncombe County Medical Society to investigate their merits or demerits. The first few days were fruitless, and by legal authority we were informed that unless we could show that they were giving medicine, they could continue their fraudulent practice under the guise of electricity and radium.

"At this time in the August 19, 1911, issue of THE JOURNAL of the American Medical Association there appeared a timely article in the 'Propaganda for Reform' department on 'Mayr's Wonderful Stomach Remedy, Another Fake Gall-Stone Cure.' This seemed to fit some of the cases which they were purporting to cure of gall-stones. After searching around a few days we found a reliable witness, who had received the 'gall-stone treatment,' as described in the above-mentioned article. [The 'treatment' here referred to consists essentially in giving the victim a massive dose of olive oil, followed by a saline. The patient is made to believe that the soapy concretions, that are discharged following this procedure, are gall-stones. —ED.]

"Warrants were then issued for these 'doctors,' charging them with *giving medicine without a license and doing a* fraudulent practice. It seems that they had been unable to secure a licensed physician. Had they been successful, I doubt if they could have been prosecuted.

"In the process of serving warrants these 'doctors' duped the officer, and, as he returned to headquarters for more information, they hurriedly left their offices and 'skipped' town.' The committee was rewarded, however, as the daily newspapers wrote up the exposure, and there was no attempt on the part of the experts to return. By ridding Asheville, however, they will be thrust on another unsuspecting public, and we hope that by calling attention to this prosecution in THE JOURNAL they will be caught and prosecuted elsewhere.

"The newspaper and various creditors secured writs for their equipment, which was found to be the cheapest of electrical appliances, and some of the patients were able to attach a portion of their fat bank account. It is believed that, in a few short weeks, they extracted several thousand dollars from our innocent townspeople.

"The *Buncombe County Medical Society directed that* we send to THE JOURNAL of the American Medical Association the above report, hoping that its appearance in the pages of THE JOURNAL will apprise other communities.

"The committee suggests that it is high time some legislative action be taken for the protection of the public against the exploiters of fake electrical methods of treatment. It is thought by our legal authority that the making of a diagnosis, giving an opinion, applying electrical treatment and charging a fee really amounts to the practice of medicine, and that it should be in licensed hands.

"We further call the attention of the profession to the fact that most of these advertising electric concerns do, as a matter of fact, give drugs, and it is no wonder that electrotherapeutic methods are in such disrepute with the laity, since any faker can legally use them.

"The committee desires to acknowledge the value of the investigations of fraudulent practices that are now being propagated by THE JOURNAL, and to call attention to this specific instance.

CONVICTIONS UNDER FOOD AND DRUGS ACT *

(Concluded from page 1373)

ROYAL LITHIA WATER

William H. Anderson of Waukesha, Wis., sold another of the so-called lithia waters, which contained an unweighable quantity of lithium. It was labeled as a cure for rheumatism, gout, dropsy, etc. It was very evidently misbranded; a charge to which the defendant pleaded guilty and was fined $25. —[*Notice of Judgment, No. 1032.*]

RADIO-SULPHO CANCER CURE

This impudent fraud, which has already been exposed in THE JOURNAL[1] was exploited by one Philip Schuch, Jr., of Denver. He also sold, as an accessory, a nostrum which he called Radio-Sulpho-Brew. Radio-Sulpho was an alleged cancer cure; Radio-Sulpho-Brew a "Blood Purifier." Analyzed by the government chemists, Radio-Sulpho was found to consist of a solution of sulphur and sodium hydroxid in water. In this connection it will be remembered that the Colorado state chemist characterized this malodorous combination as "a bad smell capitalized for a million dollars." Radio-Sulpho-Brew was found to be essentially nothing more than a solution of epsom salts. Both of these nostrums were declared misbranded on the grounds that they did not possess the therapeutic virtues claimed for them, neither did they possess radium or radio-active properties as their name would indicate. Schuch, Jr., pleaded not guilty but the jury held differently.—[*Notice of Judgment, No. 1049.*]

---

* Descriptions of ninety convictions previously reported in popular form in THE JOURNAL are issued as an illustrated pamphlet, entitled "Convictions," price 6 cents.

[1] THE JOURNAL A. M. A., Dec. 3, 1910; also "Nostrums and Quackery," pp. 68-70.

LA SANADORA

Benigo Romero was the romantic name of a "patent medicine" exploiter who did business under the firm name of the Romero Drug Company in Las Vegas, N. Mex. La Sanadora was evidently sold chiefly to Mexicans, for the label was in Spanish. It was said to cure various things from "rheumatism" to "rump ache" and "twitching eye-brows" to "cholera." Analysis showed it to contain among various things:

Opium.
Alcohol.
Chloroform.
Oil of peppermint.
Ammonium hydroxid.
Water.

It was declared misbranded on two counts. First, because the label contained no statement of the amount of alcohol, chloroform and opium in the mixture; and second, because the product *would not cure the various ailments claimed.* Romero pleaded guilty to the first count and was fined $50. The second count was dismissed on motion of the United States attorney.—[*Notice of Judgment, No. 1076.*]

TUCKER'S ASTHMA SPECIFIC

This nostrum has been exposed at various times in THE JOURNAL.[2] It is exploited by a Dr. Nathan Tucker, Mt. Gilead, O. It contains cocain and is said to be a "specific for asthma, hay fever and all catarrhal diseases of the respiratory organs." The government declared the stuff misbranded on two counts: (1) It contained cocain and the label bore no statement of the quantity or proportion of this drug; (2) it was not a specific. Tucker pleaded not guilty, but the jury before whom the case was tried declared him guilty on the first count. Tucker's lawyer filed motions in arrest of judgment and for a new trial but both motions were overruled by the court and Tucker was fined $150 and costs.—[*Notice of Judgment, No. 1077.*]

PEEBLES' EPILEPSY CURE

This nostrum is exploited by a concern called "Dr. Peebles' Institute of Health" at Battle Creek, Mich. The treasurer and general manager of this so-called institute is W. T. Bobo, M.D., a quack who advertises to cure goiter. Peebles' so-called cure consists of two preparations, his "Brain Restorative for Epilepsy and All Diseases of the Brain and Nervous System" and his "Nerv-Tonic for the Blood and Nerves." Analysis by the Bureau of Chemistry showed that the "Brain Restorative" was a solution of ammonium, sodium and potassium bromids with an alcoholic preparation of valerian, flavored with bitter almonds. "Nerv-Tonic" was a sweetened watery-alcoholic solution of vegetable products containing no material having distinctive, active characteristics. The stuff was declared misbranded because of the falsity of the therapeutic claims. The company, by its treasurer, filed a plea of *nolo contendere* and was fined $5.—[*Notice of Judgment, No. 1079.*]

DETCHON'S RHEUMATISM CURE

I. A. Detchon of Crawfordsville, Ind., sold two nostrums called respectively, "Dr. Detchon's Relief for Rheumatism" and "Dr. Detchon's Relief for Rheumatism Tablets." Both of these preparations were formerly sold under the name "Mystic Cure" and "Mystic Cure Tablets," respectively. False, misleading and extravagant claims were made for both these products such as to constitute misbranding. Analyzed by the government chemists, "Dr. Detchon's Relief for Rheumatism" was found to consist essentially of sodium salicylate, sugar and water, while "Dr. Detchon's Relief for Rheumatism Tablets" was found to consist principally of sodium salicylate. Detchon pleaded guilty to the charges and was fined $200 with costs.—[*Notice of Judgment, No. 1091.*]

DR. LINDLEY'S EPILEPSY REMEDY

This nostrum which was exploited by one A. K. Hollowell under the alias New Vienna Medicine Company, was sold as a cure for epilepsy. Some of the claims made for it were:

"Produces perfect cures."
"May be taken as long as required without any fear of harm."
"A Positive Remedy for Epilepsy, Fits, Spasms, Convulsions and St. Vitus' Dance."

Analyzed by the Bureau of Chemistry, the "remedy" was found to be a solution of bromids in water and alcohol. It was declared misbranded both because of the falsity of the therapeutic claims and because the proportion of alcohol was not given on label. The defendant pleaded guilty and was fined $200 and costs.—[*Notice of Judgment, No. 1093.*]

Correspondence

Object-Lessons on Venereal Disease

To the Editor:—In view of the recent papers and discussions on the subject of venereal disease (THE JOURNAL, Sept. 23, 1911, p. 1052) and the excellent exposé of the Interstate Remedy Co. (THE JOURNAL, Oct. 7, 1911, p. 1222). it may be of interest to describe some of the details of perhaps the first evidence, on a large scale, that far-sighted business men are awakening to the importance of the popular teaching of hygiene, and especially of combating venereal disease.

The National Cash Register Company, of Dayton, O., has about 6,000 employees in its factory. A welfare department is maintained in the interests of the employees; and every man and woman must undergo a medical examination before going on the pay-rolls; venereal disease, if detected, at once bars an applicant from employment.

In spite of the unusual precautions, the officers of the company have long felt that their factories have nearly their full quota of gonorrhea and syphilis, and this last summer it was determined to secure the best possible series of object-lessons for the instruction of their men. The text-book plates usually used for this purpose were discarded and the slides for the lectures were made from actual life and were then colored by an artist from life, many weeks being spent on this alone and every phase of the venereal diseases being reproduced with startling faithfulness.

To make the subjects still more real, a moving-picture-in-color process was used; the films, machines and operator were imported and many venereal victims were taken in motion, removing their bandages, etc., and showing the terrible results of the disease in the most striking way, the natural colors being reproduced by photography. The subjects really seem to live, breathe and move before the audience.

For the practical protection of the auditors several fakes are exposed and their methods explained, among them being the subject of the article in THE JOURNAL, October 7.

It is the purpose of the National Cash Register Company to give these lectures repeatedly in their new auditorium during working hours, the employees hearing them in detachments of about a thousand at a time, and receiving full wages while they are attending. The officers are convinced that this will eventually pay them in dollars and cents, though the lectures have already cost several thousand dollars to prepare and the wages of the men, while hearing them, will amount to several thousand more.

Other lectures on the simple physiology of digestion, respiration and circulation, etc., with practical application to the selection of wholesome foods, the prevention and care of tuberculosis, the patent medicine frauds, etc., are now being prepared in the same elaborate manner and will be presented in a similar way during the winter.

This company believes that it pays to be well and keep well, and that a workman unhappy internally is an economic loss externally—and it apparently has the courage of its convictions.

F. M. LOOMIS, Ann Arbor, Mich.

The Use of Bismuth and the X-Ray in Diagnosing Diseases of the Alimentary Tract, Etc.

To the Editor:—In May, 1899, I read, before the Chicago Medical Society, a paper entitled, "Original *X*-Ray Work and Its Value to Stomach Diagnosis," which was published in the *Philadelphia Medical Journal*, Aug. 26, 1899. THE JOURNAL commented on it Sept. 2, 1899. At that time I said, speaking of the *x*-ray: "I am within bounds when I say that the prevailing idea with the general practitioner has been that it is only of value to the surgeon . . . however, it is possible to recognize new growths, deformities, malformations, variation in the density of bone . . . calcareous infiltrations of various organs or tissues. . . . Some months ago I became convinced that I could make use of the *x*-ray in my special study of the stomach and alimentary tract, and later I made a study of the other cavities of the body. It is my pleasure to present to you the result of my experiments as to method, technic and apparatus, with brief reference to its value in stomach diagnosis. My claim is that the work is original, that the value of the method of examination is far in advance of any that we have heretofore used. By it the stomach can be definitely outlined, giving its size, shape and position. It is also possible to examine the transverse colon, fistulous tracts, uterus or bladder. This is accomplished by filling the stomach, cavities or tracts with what I have termed my bismuth emulsion. The bismuth emulsion is non-toxic, non-irritating and can be made antiseptic making it possible to fill any accessible cavity. In preparing for the skiagraphic examination . . . the stomach can be filled with the bismuth emulsion, using enough to bring the organ to the point of complete distention. . . . With the fluoroscope you will be able to note the outlines of the stomach, showing the lesser curvature. . . . The stomach can be studied from different views. . . . giving a definite idea of the normal movements of the organ and enabling us to diagnose motor insufficiency. . . . Radiographs of the stomach are unsatisfactory, because its normal movements, combined with the change in its shape and position produced by respiration [we had to expose twenty minutes at that time] makes it impossible to produce a clear outline on photographic plates. The best work is done with the fluoroscope."

In looking over medical literature I find that Rieter of Munich makes the claim that he was the first to have used this means of stomach diagnosis. This was in 1904, five years after the publication of my paper.

In January, 1908, E. G. Beck of Chicago, makes the claim to have been the first to have used the method of diagnosis in cases of fistula. Satterlee and LeWald in THE JOURNAL (Oct. 14, 1911, p. 1255), in speaking of *x*-ray examinations of the gastro-intestinal tract say that the method of employing some insoluble substance such as bismuth, etc., will soon be universally used.

WALTER B. METCALF, Chicago.

TARIFF ON SURGICAL INSTRUMENTS

To the Editor:—Is a physician returning from a trip abroad compelled to pay duty on surgical instruments purchased for his personal use? N. S.

ANSWER.—This question was referred to the Treasury Department, Washington, D. C., and the following reply was received from James F. Curtis, the assistant secretary:

"Paragraph 709 of the tariff act of Aug. 5, 1909, provides that in the case of residents of the United States returning from abroad, all wearing apparel and other personal effects taken by them out of the United States to foreign countries will be admitted free of duty without regard to the value thereof, on their identity being established. Under this provision of Paragraph 709, physicians who are residents of this country would be entitled to bring back with them free of duty all surgical instruments taken by them from this country, provided that such instruments are not advanced in value or improved in condition while abroad. If any repairs are placed on these instruments while abroad, duty would be assessed on the value of such repairs only.

"The Board of United States General Appraisers in T. D. 30,270 of Jan. 13, 1910, following the decision of the United States Circuit Court of Appeals in U. S. vs. Bernays (158 Fed. Rep. 792), held that only such articles as were in the nature of wearing apparel and similar personal effects necessary or appropriate for the use of the persons having the same in possession for the purpose of the journey, might be included within the exemption of $100 allowed under Paragraph 709 to returning residents of the United States.

"The department's former construction of the said paragraph permitted such residents to bring back with them, free of duty, articles to the value of $100 acquired abroad with little regard as to the character thereof, but subsequent to the board's decision above referred to, this practice was changed to conform to such decision. Surgical instruments purchased abroad by physicians cannot be included within this exemption unless they are necessary and appropriate for the purposes of the journey and for personal comfort and convenience.

"Surgical instruments if composed wholly or in part of metal would probably be dutiable under the provisions of Paragraph 199 of the said act at the rate of 45 per centum ad valorem. Surgical scissors would be subject to duty as scissors under Paragraph 152 as follows: valued at not more than 50 cents per dozen, 15 cents per dozen and 15 per centum ad valorem; valued at more than 50 cents and not more than $1.75 per dozen, 50 cents per dozen and 15 per centum ad valorem; valued at more than $1.75 per dozen, 75 cents per dozen and 25 per centum ad valorem. Other surgical instruments would be dutiable under appropriate paragraphs of the tariff according to the component material of chief value."

STROPHANTHUS TINCTURE TENDS TO DECOMPOSE IN WATER

To the Editor:—In your interesting department of therapeutics, in the series you have been printing on prescription writing, I find under the head of "Incompatibility," October 14, page 1289, the following statement: "Strophanthus in the form of the tincture should not be prescribed in solutions containing water. It slowly forms a toxic substance when in water solution. I ask for further information, as this chemical action is not familiar to me.

N. D.

ANSWER.—We quoted this from Osborne's book on "Materia Medica and Pharmacology," ed. 1906, p. 92. The tincture of strophanthus may deteriorate even when undiluted. When diluted with water, fermentation takes place, and decomposition, souring and cloudiness soon occur. The tincture of digitalis, for instance, will stand much greater dilution and will keep for a much longer time than will the tincture of strophanthus without deterioration. The official strophanthinum is a glucosid or a mixture of glucosids, and is probably not often a single active principle, although a crystalline strophanthin has been separated and can now be obtained. This mixture of glucosids in the strophanthus of the official tinctura strophanthi seems to undergo changes when diluted with watery solutions and allowed to stand in an ordinary medicine bottle. It has been stated that such solutions have produced poisoning, although the term poisoning may be a little strong. As to the cloudiness caused by the addition of water to tincture of strophanthus, it is quite probable that this is due to the fixed oil which strophanthus contains; the seeds are stated to contain 30 per cent. of such an oil, as well as kombic acid.

METHOD OF APPROXIMATE ESTIMATION OF INDICAN IN URINE

To the Editor:—I noticed in THE JOURNAL (Oct. 21, 1911, p. 1386), a request for a method of quantitative estimation of indican in the urine. About ten years ago I suggested a very simple and fairly accurate method.

To 10 c.c. of the urine add 1 c.c. of a solution of lead acetate (25 per cent.) and filter through a double filter. To the filtrate add an equal volume of Obermayer's reagent (2 gm. of ferric chlorid to the liter of strong hydrochloric acid) and 2 c.c. of chloroform. Invert the tube several times, until the coloring of the chloroform asumes maximum intensity. If only a slight coloration appears the amount of indican is very small, and further testing would be useless. If the indican is present in appreciable amounts, however, add from a dropper, drop by drop, a solution of potassium chlorate (34.6 gm. per liter) until the color is discharged. The number of drops of the chlorate solution required to discharge the color may be taken as an index of the amount present. Normally, one to two drops are sufficient.

A. ROBIN, Wilmington, Del.

AVOID OILS AND ALCOHOL IN HOOKWORM TREATMENT WITH THYMOL

To the Editor:—For the treatment of hookworm disease I find that Osler's "Practice of Medicine" gives dangerous advice. The editions of 1900 and 1907 advise castor oil, and the 1907 edition, whiskey or brandy. A. C. Fisher, Emmerton, Va.

Comment.—An examination of the editions referred to shows that our correspondent is correct. We also find this dangerous advice given in the 1911 edition. Although we have called attention to this danger previously in the columns of The Journal, it is well to speak of it again. The danger to which our correspondent refers is that the thymol which has been given to kill the hookworm parasites may dissolve in the oil or alcohol, and then be absorbed by the body with more or less toxic—perhaps serious—effects. All oils and alcohol are to be scrupulously avoided until the thymol has passed out of the intestinal canal.

ELIMINATE THE TERM "ALLOPATH"

To the Editor:—In support of the committee of the Fulton County (Ga.) Medical Society, I beg to say that the word "allopath" was invented by Hahnemann, as was the epithet "old school" invented by so-called "eclectics," to apply to regular practitioners. See Webster's Unabridged Dictionary. Both epithets are used almost exclusively by irregulars and their friends.

A. G. Field, M.D., Des Moines, Iowa.

The Public Service

Medical Department, U. S. Army

Changes during the week ended Oct. 28, 1911.

Banister, W. B., lieut.-col., Oct. 20, in charge chief surgeon's office, central division.

Sheep, W. L., lieut., granted leave of absence for twenty days, about Oct. 20, 1911.

Stone, F. P., dental surgeon, reports arrival Oct. 16, 1911, Fort Morgan, Ala., for temporary duty.

Hart, W. L., captain, arrived at San Francisco, Oct. 19, from Manila.

Kean, J. R., lieut.-col., Oct. 23, reports departure from Washington, D. C., en route to Paris, France, to attend the International Sanitary Conference to meet there Nov. 7, 1911.

Kerr, R. W., lieut., ordered to Fort D. A. Russell, Wyo., at expiration of leave of absence.

Koyle, F. T., M.R.C., when *Kilpatrick* goes out of commission will return to his station, Fort H. G. Wright; arrived Oct. 24, 1911, for duty.

Sheep, W. L., lieut., left Fort Ethan Allen Oct. 20 on leave of absence for twenty days.

Wing, F. F., dental surgeon, Oct. 19, arrived at Fort Lincoln for temporary duty.

Pascoe, J. B., M.R.C., Oct. 20, returned to Fort Wood from leave of absence.

Chase, C. L., M.R.C., Oct. 19, left Fort Oglethorpe, Ga., for duty at Fort Dade, Fla.; arrived Oct. 22, 1911.

Kerr, R. W., lieut., Oct. 18, on leave of absence for two months; relieved from duty on transport *Sherman*.

Lewis, W. F., major, Oct. 16, returned to presidio, Monterey, Cal., from leave of absence.

Page, Henry, major, Oct. 15, arrived at San Francisco Oct. 16 on leave of absence for four months.

Pinkston, O. W., captain, leave already granted him is extended fifteen days.

Pariseau, G. E., lieut., detailed as member of the board at Panama to examine candidates for second lieutenant, Philippine scouts, vice Mason, C. F., lieut.-col., relieved from above board.

Maynard, E. B., M.R.C., reports his return to San Antonio, Tex., Oct. 21, from leave.

Griffin, A. M., M.R.C., Oct. 22, arrived at Fort Riley for duty.

Voorhies, H. G., dental surgeon, Oct. 21, returned to Jefferson Barracks, Mo., from leave of absence.

Gentry, E. R., lieut., relieved from duty at Fort Leavenworth, Kan., in time to take transport to sail from San Francisco Dec. 5, 1911, for the Philippine Islands, for duty on the board for the study of tropical diseases.

Lynch, Charles, major, will proceed to Pittsburgh on special duty in connection with the American Red Cross, and on its completion will return to his station in this city.

Boehs, C. J., M.R.C., Oct. 21, arrived at Fort Banks for duty.

Ingalls, R. E., dental surgeon, will leave Fort Douglas, Utah., Nov. 1, for Forts Yellowstone, W. H. Harrison and Missoula.

Richardson, W. H., captain, relieved from duty in the Yosemite national park and ordered to return to his station, Fort Miley, Cal.

Hart, W. L., captain, Oct. 22, arrived at Fort Sam Houston, Texas, for duty.

Shockley, M. A. W., major, Oct. 24, reports his arrival at Fort Niagara, N. Y., for duty.

The following named medical officers are assigned to and ordered to join the station set opposite their names: Foucar, F. H., lieut., Fort Du Pont, Del.; Whitham, J. D., lieut., Fort Monroe, Va.; Clark, A. P., lieut., Fort Williams, Maine; Willis, J. M., lieut., Fort Snelling, Minn.; Coulter, J. S., lieut., Amb. Co. 3, Fort Leavenworth, Kan.

McAlister, J. A., dental surgeon, on completion of his duties at Fort Bliss will proceed to San Antonio, Texas, to prepare his dental equipment for shipment and then return to his station, Fort Leavenworth.

Hill, F. R., lieut., granted leave of absence for one month, about Nov. 1, 1911

Diagnostic Aids in Surgery of the Renal Pelvis and Ureter, with Special Reference to Pyelography

Dr. W. F. Braasch, Rochester, Minn.: Radiography, cystoscopy, meatoscopy and ureteral catheterization are valuable aids in diagnosis, but may give an erroneous impression and often be insufficient. With pyelography one may be able to demonstrate changes in the outlines of the pelvis and ureter which accompany most surgical conditions of the kidney and ureter. Hydronephrosis may be accurately determined by the pyelograph. It is particularly valuable with small distention and with marked constriction of the ureter. By using these data one is able to identify renal shadows by inflammatory changes seen in the pelvis and ureter. Stone in the ureter is recognized by the mechanical dilatation above it. Deformity caused by tumor of the kidney may be demonstrated in about two-thirds of the cases. There is not as yet a widespread adoption of the pyelograph, largely because of a lack of technical facility. There is never permanent injury resulting from its use.

Dr. John T. Geraghty, Baltimore: We have used this method of examination for about a year and a half, and have found it of the greatest value in a certain class of cases. It gives a most graphic and striking illustration of the stomach, dilatation of the calyx, twists of the ureter, etc. So far as the kidney and pelvis itself are concerned, we have not been able to get as much information from it as Dr. Braasch has. With the use of the ureteral catheter, with the employment of the pyelograph to estimate the renal function, and with the chemical and microscopic characters of the urine, we can place kidney surgery on just as accurate a plane as any other branch of medicine or surgery.

Diagnosis of Prostatic Obstruction

Dr. Bransford Lewis, St. Louis: I consider the following features as essential in a diagnosis of such conditions, not only for the analytical study of the case, but as a working basis for treatment: 1. Hypertrophy or not? 2. If so, is it causing obstruction? 3. The amount of obstruction so produced. 4. The form and nature of the condition producing the obstruction. 5. The physical and functionating condition of the allied organs, particularly kidneys and cardiac system.

All of these points should be considered and determined accurately before attempting to decide as to the treatment or operation, except for such measures as emergency treatment may call for to relieve acute retention or sepsis, etc.

Cancer of the Prostate

Dr. Robert C. Bryan, Richmond, Va.: Primary cancer of the prostate may follow one of two general types, namely, the scirrhous and the glandular. Cancer is not infrequently associated with beginning hypertrophy, may originate in a normal and atrophic gland, or in an organ which has been the seat of a chronic prostatitis. One lobe or the entire gland may be involved. The infiltration may form foci so small as to be detected only by the microscope. Carcinoma of the prostate does not result as a degeneration of a previously benign adenomatous process. In every case of senile prostatic hypertrophy the fact of the possible existence of carcinoma must be borne in mind. The prostate itself causes no symptoms in the early stages of carcinoma; the subjective symptoms are given out by the bladder and pelvic organs. The invasion of the disease is so gradual, and the symptoms modified so progressively, that there is an unconscious adjustment of the patient to the condition. The treatment is divided into preventive and curative. Medical treatment is not to be entertained. There seems to be little virtue in the Roentgen ray, Finsen light or radium therapy. Bilateral castration is the operation of choice. In twenty-two cases of twenty-six operated on, the patients regained the bladder functions. The suprapubic operation is to be condemned as the prostatic urethra comes away and gives an unusually good opportunity for the escape of carcinomatous juices. In the second stage of the disease the operator must base his judgment for surgical attack on the degree and type of pathologic invasion.

The Influence of Stricture of the Urethra on the Development of Hypertrophic Changes in the Prostate

Dr. Hugh Cabot, Boston: Stricture of the urethra is markedly antagonistic to the development of hypertrophy of the prostate, owing to the long standing chronic prostatitis which it causes; therefore, no case of stricture of the urethra in later life, in the absence of enlargment of the prostate may be assumed. The recognition of this fact is important in the management of retention of urine in later life; it has not been sufficiently understood. The management of retention of urine due to stricture, and of that due to hypertrophy of the prostate is radically different and each condition has markedly a different prognosis.

DISCUSSION ON PAPERS OF DRS. LEWIS, BRYAN AND CABOT

Dr. E. G. Mark, Kansas City, Mo.: We can still further add to the comprehensive diagnosis of hypertrophy of the prostate by means of bimanual palpation. Where we have obstruction, be it from hypertrophy or contraction at the neck of the bladder, we should get away from the idea that the residual urine is increased. In contraction of the vesical neck, we are dealing with a neck below the age of those patients in whom we deal with hypertrophies. We have a compensatory hypertrophy of the musculature of the bladder, and therefore, a lessened residuum.

Dr. Henry J. Scherck, St. Louis: It is important to know when to operate in a case of hypertrophy of the prostate. I have seen a number of cases in which a very large prostate which could be palpated through the rectum produced very slight symptoms of obstruction. It is not always a large prostate that causes obstructive symptoms. Not long since I unfortunately removed a man's prostate, thinking the obstruction was due to enlargement of that organ, but the obstructive symptoms did not disappear. Subsequently it was found that this man had arteriosclerosis of the cord, as determined by a neurologist, which produced the bladder symptoms.

Dr. William N. Wishard, Indianapolis: The cystoscope may become a clumsy instrument in the diagnosis of prostatic hypertrophy. The prostate changes and increases in size; the urethra is usually elongated; it also has changed its angle, and in the introduction of the cystoscope, whose shaft is straight, the end of the shaft where the window of the cystoscope rests must be passed far beyond the vesical orifice and above the obstruction, or it is hard to get any view at all. The canal which, before the introduction of the instrument, was curved, is now straight and on account of the displacement of the vesical orifice there is produced a certain amount of bulging which is misleading.

Dr. W. F. Braasch, Rochester, Minn.: I would call attention to the value of urethroscopic examination in the diagnosis of hypertrophy of the prostate. I am in the habit of using a flexible instrument. It is also of value in the diagnosis of carcinoma involving the prostatic urethra. Carcinoma of the prostate in the majority of cases can be diagnosed by rectal palpation.

Dr. William Britt Burns, Memphis: Dr. Cabot has called attention to the lack of enlargement of the prostate in the presence of stricture of the urethra. That is a point that has escaped my attention, and I would like to know how that can be verified. A short time ago I had a patient with a very tight stricture of the urethra. I was not able to introduce the smallest filiform bougie. I resorted to suprapubic cystotomy, and in going through the neck of the bladder and opening the urethra in that direction, I was struck with the size of the prostate and debated for a short time as to the advisability of removing the prostate, but on account of the condition of the patient I did not do so. In that case there was a large and strong annular stricture at the neck of the bladder.

Dr. John T. Geraghty: I find that carcinoma of the prostate does not arise from a degeneration of the hypertrophied tissue, but it occurs in the portion of the prostate that is left behind. The posterior commissure never undergoes hypertrophy, and you will find there a plateau of tissue when cancer comes, and when associated with hypertrophy you will find cancer on the posterior surface. That is a point of practical importance. When you are doing perineal prostatectomy and have to cut through a dense layer of tissue before you come to the typical hypertrophied lobules, you may be sure you are dealing with cancer because it is the only condition which will give that picture, and it will help us in making a diagnosis if we have not done so before operation.

Dr. William Billington, Birmingham, Eng: With regard to the operative treatment of hypertrophy of the prostate, in England the suprapubic method is practiced more extensively than the perineal. Very large, soft, adenomatous prostates can easily be enucleated through a suprapubic incision, and the patients do well. The cases of small carcinomatous prostate, and those with contraction at the neck of the bladder, present grave difficulties if we attempt to enucleate them by the suprapubic route.

Operative Treatment of Gonorrheal Epididymitis

Dr. Francis Hagner, Washington, D. C.: I do not operate in every case of gonorrheal epididymitis, as the milder forms often recover promptly under appropriate expectant treatment. Until operative procedures were resorted to in acute gonorrheal epididymitis very little seemed to have been known of the gross pathologic appearance of this condition. In some cases on exposure of the epididymis multiple abscesses can be distinctly made out before puncture; in others abscesses cannot be made out until punctures are made. Eighty per cent. of my cases have had pus present in the epididymis, varying from a few drops to 1 and 12 drams, and yet the text-books on surgery state that gonorrheal epididymitis very rarely goes on to suppuration.

DISCUSSION

Dr. J. W. Handley, Nashville: I have had occasion several times to make incisions in the tunica vaginalis in cases of gonorrheal epididymitis, and have given my patients relief. The ideas Dr. Hagner has advanced in favor of operation are logical and worthy of serious consideration.

Dr. Hugh Cabot, Boston: We have operated in about thirty cases by Dr. Hagner's method, with gratifying results. I desire to lay stress on the results to the gonorrheal process by drainage of the epididymis, because it has seemed clear that in a certain proportion of cases—say 25 per cent.—drainage of the epididymis very definitely shortens the attack.

Dr. Joseph Rilus Eastman, Indianapolis: I would like to know whether Dr. Hagner has found the colon bacillus in any of his cases of gonorrheal epididymitis. I have found colon bacilli in abscesses which ensued on what seemed to be a gonococcal epididymitis.

Dr. Perry Bromberg, Nashville: Shortly after Dr. Hagner described his method in the *Annals of Surgery*, 1908, I tried it in one case, and the relief was so great that I have since adopted it as a routine method. I have done the operation more than twenty-five times, and my results have been excellent.

Dr. F. R. Hagner, Washington: I have not found the colon bacillus in a single case, but I do not deny that it may have been found by others.

Relation of Renal Activity to Surgical Operation

Dr. E. O. Smith, Cincinnati. The success or failure of a major operation depends largely on the activity of the kidneys, of course, barring faulty technic and bad surgical judgment of the operator. The functional activity of the kidneys may be influenced by the shock incident to a major operation, by the anesthetic, by trauma to one or the other kidney, by calculi, or by ureteral obstruction from any cause. There are three distinct periods of every surgical case that require special care and attention: the preoperative period, the operation and the postoperative period. It is best to make a further study of the functional activity of the kidneys before operation. This is based on the observations that normal kidneys remove from the circulation certain products that have been introduced within a certain time, and that marked deviations from this time represent abnormal kidneys. Operation should be done as rapidly as consistent with good work, for the longer the operation the greater the shock, and the greater the shock the greater the circulatory disturbance, and in consequence of which the blood-supply to the kidney is diminished, a very apparent cause of renal inactivity. Immediately following the anesthetic the patient should be given oxygen inhalation. In old people and bad risks this should be continued for several hours. Hiccough and persistent vomiting following operations are indicative of diminished renal activity and should be looked on as a warning rather than an independent complication calling for special treatment. When anuria does occur, the best treatment is fluid introduced into the veins, sweating and morphin. We have always used saline solutions, but Fischer's solution and alkaline solution are far more effectual.

DISCUSSION

Dr. William N. Wishard, Indianapolis: A study of the urine prior to operation, where it is found to be abnormal, is considerably influenced by the various preoperative or preparatory measures to which Dr. Smith has called attention. The specific gravity and the percentage of urea and the general condition of the urine are helpfully influenced by drainage. In a certain class of cases I drain the bladder, where it is possible for two or three days or longer prior to operation. We do not always estimate the importance of shortening the period of anesthesia in its relation to renal function.

Dr. Hugh Cabot, Boston: In our practice in the last two years in operations on the prostate, we have used spinal anesthesia as the anesthetic of election where the kidney function was below a fair standard, and many patients have recovered who we feel would not have recovered under general anesthesia. We have used gas and oxygen with excellent results, and in cases of damaged heart that anesthetic is to be preferred.

(To be continued)

MEDICAL SOCIETY OF PENNSYLVANIA

Sixty-First Annual Meeting, held at Harrisburg, Sept. 25-28, 1911

(Concluded from page 1381)

Traumatic Surgery of the Hand and Foot

Dr. James Jefferson, Johnstown: The most important feature in traumatic surgery of the hand is the care of severed tendons. In suturing tendons, the approximation has much to do with the efficiency of the repair. In subsequent fixation the part must be placed in such position as to avoid tension on the sutures. The best method of treating metacarpal fractures is by a long palmar splint with adhesive strips at the wrist for counter extension, and two strips of adhesive applied to the finger after the manner of Buck's extension. The severely crushed finger should be cleansed thoroughly, the soft structures replaced, and a hot bath of 1 to 4,000 corrosive sublimate applied. There is a great temptation to amputate, but it pays to take time and patience to avoid this. For sprains of the ankle my custom is to apply a plaster cast with the foot at right angles to the leg, and follow this later by strapping, after the method of Gibney.

DISCUSSION

Dr. J. Stacey John, Bloomsburg: Roentgen-ray examination in all cases of injuries of the hand and foot should be made to determine if any of the tendons have been severed. If so they should be sutured with catgut.

Dr. Americus R. Allen, Carlisle: The first thing that deserves consideration in these injuries is conservatism. When there is infection there should be free incision and immobilization. In dressing cases of fracture I use a small splint made of adhesive plaster with a small strip of pasteboard in between, and it answers very well.

Treatment of Backward Displacements of the Uterus

Dr. Xavier O. Werder, Pittsburgh: A simple uncomplicated uterine displacement rarely justifies operative treatment, because this malposition is usually a harmless condition. When symptoms accompany a uterine displacement we should first carefully search for some pelvic complications which are usually responsible for the disturbances, and in the absence of such affections, carefully examine into the general condition of the patient, and especially look for some manifestation of a disordered nervous system which is often at the foundation of this trouble. When in doubt, as of necessity we often are in this class of cases, a temporary correction of the displacement by means of a well-fitting pessary will often determine whether the cause of the ailment can justly be attributed to the uterus or to some derangement of the general health of the patient. Thus the pessary will often prove a valuable diagnostic as well as therapeutic agent.

DISCUSSION

Dr. Lowell M. Gates, Scranton: While it is true that not all cases of retrodisplacement of the uterus need immediate operation at first, sooner or later they will. In time they will produce symptoms of interference with the proper circulation of the blood in neighboring organs. We must always consider the type of the patient. A phlegmatic woman in the ordinary walks of life will go around for years with a retrodisplacement of the uterus without paying any attention to it, while the neurotic is made uncomfortable.

Secondary Repair of the Perineum by the Emmett Method

Dr. Henry D. Beyea, Philadelphia: There is much evidence of a tendency to discredit the value of the Emmett operation for secondary repair of the perineum. There is no operation in surgery that is more difficult of understanding or requires more study and surgical skill in its performance than this one. It is essential to practice every detail of the operation as taught by Emmett, even to the needle and suture material. Properly practiced, it is the only anatomically and surgically correct, and the most efficient method of restoration of the injured pelvic floor and the relaxed vaginal outlet.

DISCUSSION

Dr. Theodore B. Appel, Lancaster: In my work on the perineum the results of the Emmett operation have not been very satisfactory. My object in these cases is to get after the weakest point. I question whether you can do that by the Emmett operation

Dr. J. W. Luther, Palmerton: It is a mistake to try to apply one operation to all cases. If a distinct sulcus laceration can be demonstrated, the Emmett operation is the operation of choice. There are many cases of relaxation of the pelvic floor either with or without laceration. In these cases, when a distinct sulcus tear cannot be demonstrated, I think the Hegar operation superior to the Emmett.

Dr. W. Wayne Babcock, Philadelphia: There is no doubt that Emmett's operation has served a very useful purpose in the development of gynecologic surgery. It is a gynecologic and not a surgical procedure. The relaxed perineum is a condition very similar to hernia. By bringing its walls in apposition we can repair a perineum that is relaxed in just the same way that a hernia is repaired. There is no reason why we should not expose the various layers of tissue and bring them together.

Dr. J. M. Baldy, Philadelphia: My own impression has been that an operation is always surgical, providing the man knows how to do surgery. The trouble with those who criticize the Emmett operation is that they do not know how to do it. They show this by their criticism. The fault has been with the gentlemen who have tried to modify the Emmett operation. They have not done the Emmett operation. There is no such thing as a relapsed perineum without a laceration.

Dr. R. C. Norris, Philadelphia: The Hegar operation is suited only to women who will not again bear children, while the Emmett operation is adapted to child-bearing women. The difficulty lies in the lack of knowledge of the anatomy. We should go back to anatomy and study the anatomic basis of these operations; then we shall learn the true principle involved.

Essentials in Surgery

DR. J. M. WAINWRIGHT, Scranton: Surgeons could very well devote more time to the study of how to avoid operations which must end fatally, how to make all operations more safe, and how to diminish postoperative discomfort. In the ideal stage of surgery there would be no postoperative deaths, which now result either because the operation has been bungled or else because death was inevitable in spite of operation. In the latter case we have deluded ourselves into thinking that the operation would give the patient the last chance, whereas, in fact, all the operation did was to hasten the end. We need to make marked improvements in reference to the question of the safety of operating. We must learn among other things: how to avoid influencing the blood-pressure, and also how to use the anesthetic. Something must be done to make convalescence more pleasant. Patients do not get vitally interested in surgical feats performed while under the anesthetic, but they are vitally interested in the discomfort they suffer after the operation.

Estimation of Vital Resistance of Patient with Reference to Possibility of Recovery

DR. J. C. BLOODGOOD, Baltimore: For estimating the resistance of the individual we have very few scientific methods and instruments of precision as compared to those which the engineer possesses. In estimating the factors of vital resistance there are two large problems, one of diagnosis and one of treatment. The patient must be under observation from beginning to end and we must be changing our methods in order to meet the indications. As we have progressed in surgery and eliminated the grosser problems we come to-day to problems of the most minute detail. This relief with recovery depends on the estimation of the vital resistance of the patient before, during and after operation. When we come to estimate the actual factors in the resistance of the individual, science is small as compared to the art. We have to consider, first, the individual; second, the operation; and, third, the disease. Whenever we can estimate that the relief of the burden from the disease is greater than the burden we are going to place on the patient by an operation, the chances for a cure are very great. In regard to anesthesia, my personal experience in the last year has demonstrated that operations can be done under nitrous oxid on handicapped individuals, operations of a greater magnitude with the risk tremendously less than the same operation on the same individual under ether. During the operation the surgeon and the anesthetist work together, estimating the factors of shock, following pulse and respiration, and the surgeon must learn when to stop. There are many operations which do not need to be finished, and, I think, more careful observation will teach us when to stop in some of these operations of greater magnitude on handicapped individuals; we will perform the operation in two or three stages. The higher cortical centers are the least important things concerned as factors of safety.

DISCUSSION

DR. EDWARD MARTIN, Philadelphia: I take exception to the point that the higher cortical centers are the least important ones as factors in the safety of the patient. The ego, the individual aside from the physical, has an absolute dominating control over every function of the body, and by no means is the least important part of the attitude of absolute optimism on the part of the surgeon himself; his assistants and all those professional people who come in contact with that patient. Many a time, where the case was easily balanced, the victory has been won by that optimism and belief in recovery by which the patient has been properly influenced before and after the operation.

DR. HAROLD J. GIBBY, Pittston: One of the most important points, aside from the physical condition, is the temperament of the individual. The individual who resists the anesthetic, who is of a depressed nature, is sure he is going to die, is often a very poor subject. Another thing is the importance of diagnosis—to find out just how much has to be done and how much work can be done at the one sitting.

The Influence of Various Anesthetics in Determining Mortality

DR. GEORGE M. LAWS, Philadelphia: Surgical anesthesia is easy to obtain with chloroform; more difficult with ether, and most difficult with nitrous oxid, and statistics show that their relative safety is in reverse order. At the hospital of the University of Pennsylvania nitrous oxid followed by ether has been the routine anesthetic for years, and a continuance of our favorable result convinces us that ether pneumonia can be eliminated by proper application of this method. Whether or not a general anesthetic should be given when shock is present depends largely on an accurate estimate of the psychic element. The horror of ether is one of the greatest obstacles to modern surgery, as it leads the patient to defer operation. Therefore an anesthetic which is more pleasant to take has much to commend it. Ethyl chlorid has about the same range of utility as nitrous oxid, but its mortality rate, which is distinctly higher than that of chloroform, makes its use rarely justifiable. Nitrous oxid followed by ether given by the drop method overcomes practically all the objections to ether alone.

DISCUSSION

DR. WILLIAM L. ESTES, South Bethlehem: The principal thing in every anesthetic is the person who gives it. This implies that the man or woman of experience will, as a rule, adopt the anesthetic and regulate the quantity of anesthetic with reference to the patient. The next point in giving the anesthetic is the psychic state of the patient. Nephritis, especially the chronic kind, is not a contra-indication to ether.

DR. G. W. GUTHRIE, Wilkes-Barre: I believe in ether, and yet I am satisfied that the ultimate dangers of ether are sometimes overlooked. The drop method is the best method of giving ether.

How Long Should Patients Remain in Bed After Various Operations?

DR. ROBERT T. MILLER, JR., Pittsburgh: We cannot establish any law or precedent that may be safely followed in deciding the question as to how long patients should be kept in bed after operation. It is necessary to eliminate all purposeless effort and have the patient concentrate his whole strength on the problem of recuperation. This means absolute rest in bed. This may be required for two days, two weeks or two months. Exceptions to this are found in the case of elderly people, as regards pneumonia and uremia, both of which conditions may be warded off by postural change.

The Prevention and Treatment of Complications in Gastro-Intestinal Surgery

DR. DONALD GUTHRIE, Sayre: Success in this work depends more on the strict attention to details, which are often regarded by some surgeons as minor and unimportant, rather than on any unusual dexterity which may be displayed in the operating-room. The results of the surgeon who operates on the diagnosis of somebody else and who never sees his patients after operation can never be so good as those of the man who works up his cases for himself, who develops a technic of his own, and who carefully watches and treats such cases during their convalescence. The most common complications after operation on the gastro-intestinal tract in the order of their frequency are shock, acute dilatation of the stomach, pneumonia, adynamic ileus, embolism, fatty degeneration of the liver and peritonitis. In most of the well-managed operating-rooms the giving of an anesthetic is entrusted to a nurse specially trained and not to the youngest intern, who may be more interested in the steps of the operation than in the patient. The man who has a permanent force in his operating-room can do better work in all branches of surgery, especially gastro-intestinal surgery.

DISCUSSION

DR. W. L. RODMAN, Philadelphia: I am sure it would be much better for our patients if the amount of anesthetic given were reduced after the peritoneal cavity has been opened. I have been in favor of female anesthetists for the past ten years because they are more timid and see danger quicker than

Medical Education and State Boards of Registration

COMING EXAMINATIONS

ARKANSAS: Regular, Little Rock, November 14. Sec., Dr. F. T. Murphy, Brinkley; Homeopathic, Little Rock, November 14. Sec., Dr. P. C. Williams, Texarkana.

CONNECTICUT: Regular, City Hall, New Haven, November 14. Sec., Dr. Charles A. Tuttle, 196 York Street; Homeopathic, Grace Hospital, New Haven, November 14. Sec., Dr. Edwin C. M. Hall, New Haven; Eclectic, Hotel Garde, New Haven, November 14. Sec., Dr. Thomas S. Hodge, 19 Main Street, Torrington.

FLORIDA: *Regular, Jacksonville, November 7-8. Sec., Dr. J. D. Fernandez.*

LOUISIANA: Homeopathic, New Orleans, November 13. Sec., Dr. J. T. Crebbin, 1207 Maison Blanche Building.

MAINE: City Council Rooms, Portland, November 14-15. Sec., Dr. F. W. Searle, 776 Congress Street.

MASSACHUSETTS: State House, Boston, November 14-16. Sec., Dr. Edwin B. Harvey.

NEVADA: *Carson City, November 6. Sec., Dr. S. L. Lee.*

TEXAS: Fort Worth, November 14-16 (change of date from previous notification). Sec., Dr. J. D. Mitchell.

WEST VIRGINIA: Hotel Waldo, Clarksburg, November 13-15. Sec., Dr. H. A. Barbee, Point Pleasant.

Massachusetts September Report

Dr. Edwin B. Harvey, secretary of the Massachusetts Board Registration in Medicine, reports the oral, practical and itten examination held at the State House, Boston, Septem- 12-14, 1911. The number of subjects examined in was total number of questions asked, 70; percentage required pass, 75. The total number of candidates examined was of whom, 40 passed, including 3 osteopaths, and 21 failed. ding 4 osteopaths and 3 non-graduates.

Book Notices

A TEXT-BOOK OF MEDICINE. By G. Dieulafoy, Professor of Clinical Medicine at the Faculté Authorized English *Translation from the* "Manuel de pathologie interne" by V. E. Collins, M.D., M.R.C.S., L.R.C.P., and J. A. Liebmann, Ph.D., M.A., LL.D. *In two volumes.* Volumes I and II. Cloth. *Price, $12. Pp.* 2081, with 105 illustrations. *New York:* D. Appleton & Co., 1911.

The English translation of this popular French treatise will be welcomed by English-speaking physicians. The fact that fifteen editions of the book have appeared in the original language is sufficient evidence that it is fulfilling the purpose of a work on practice by a single author. Dieulafoy has adopted a simple classification of diseases of the different systems and writes from his personal experience rather than in a didactic text-book manner, frequently giving hypothetical or actual cases to illustrate a disease or a method of handling and treatment. This is a satisfactory and comforting method to the physician who turns to a text-book for information on the management of his cases. The author gives no prescriptions but suggests drugs and measures, outlining as far as possible a complete scheme of treatment and management in the various affections. The work has numerous charts, cuts and colored plates illustrating the pathology. The English edition is in two volumes and mechanically is well rendered.

OPHTHALMIC MYOLOGY. A Systematic Treatise on the Ocular Muscles. By G. C. Savage, M.D., Professor of Ophthalmology *(Defects of the Eye)* in the Medical Department of Vanderbilt University. Second Edition. Price, $4. Pp. 685, with 84 illustrations. G. C. Savage, 137 Eighth Avenue, Nashville, Tenn., 1911.

This well-known work on the extrinsic and intrinsic muscles of the eye having reached a second edition, has been considerably enlarged by the addition of ninety-one pages to the first chapter and the insertion of twenty-three new cuts. Moreover, the practical chapters, 2 and 12, have had such corrections and additions made to them as seemed to be necessary to elucidate the theorems and hypotheses which the author set forth in his first book. These comprise the fundamental principles of ocular rotations and include chapters on orthophoria, heterophoria, esophoria, exophoria and cyclophoria. The attention of the reader is called to the chapters on the paralyses and pareses of the ocular muscles, and to the following chapter which in an original manner discusses the muscles of the iris and of the ciliary body, particularly in their relations to accommodation, convergence and other normal and abnormal movements of one or both eye-balls.

A MEDICAL HISTORY OF THE STATE OF INDIANA. By G. W. H. Kemper, M.D. Cloth. Price, $2.50. *Pp. 393, with illustrations.* Published by the Author, Muncie, Ind.

This volume contains the articles which the author contributed to the *Journal of the Indiana State Medical Association* during 1909-1911 while he was chairman of the committee on necrology. There is an interesting introduction by Dr. Brayton of Indianapolis. The chapters on the *early* medical history of Vincennes and Indiana are full of valuable historical material, as are the succeeding chapters dealing with the early history of various localities. There are chapters on the state society, on epidemics and health laws, *war history, and* an alphabetical list of deceased physicians, together with biographical notices in a number of *instances. Pictures of a* number of the more prominent physicians are inserted. As a source for reliable historical material, *Dr. Kemper's book* will acquire an increasing value as years go on. The example he has set for state medical history should be *followed in other* states.

a man. I would like to know, however, what would be the legal responsibility of the surgeon whose patient dies on the table while the anesthetic is being given by a trained nurse. I do not think the diploma of a trained nurse allows her to give poisons. The thing that has brought me best results in my work is the administration of morphin and atropin one hour before operation, and the next best thing is postoperative lavage.

Dr. Charles H. Frazier, Philadelphia: I happened to consult a lawyer with regard to the legal status of an official anesthetist, prior to the employment of a female nurse anesthetist at the University Hospital and was assured by him that the hospital authorities were entirely justified in employing her and would not be subject to damage, providing they realized that in the employment of this special anesthetist they were doing it for the best interest of their patient. We should try to have a woman give ether and ether alone. It seems scarcely fair to a professional anesthetizer to have patients brought in to her and have her instructed to give the anesthetic before she has had an opportunity to go over them. She should have a list of patients to be operated on the day before operation so that she may see them, inquire as to the nature of the operation to be performed, look into the history of the case and make some examination, perhaps of the heart or lungs, before the patient is brought to the operating-room for operation.

Dr. John B. Roberts, Philadelphia: I believe that women do many things better than men, but I believe that all anesthetists should be those qualified to practice medicine; qualified to determine whether the patient has a good or bad heart, whether good or bad kidneys.

Dr. Charles E. Thomson, Scranton: I do not believe that all our troubles have ended with anesthetics when we have introduced nurses to administer them, but I think that they are so far advanced, so much better than anything we have ever heretofore enjoyed, that we are making real progress in handing over our anesthetics to trained nurses. I mean nurses who have been trained to give anesthetics.

Dr. George W. Guthrie, Wilkes-Barre: As to giving poisons, the nurse is authorized to give hypodermics of atropin and strychnin in the absence of the doctor, whereas the anesthetic is never given unless the doctor is present.

Dr. C. J. Cummings, Williamsport: I would not have it go out that a woman can give an anesthetic better than a doctor. I do not believe that should be accepted.

Dr. G. E. Shoemaker, Philadelphia: This question is a practical one in our hospitals only and does not refer to the trained nurse in general practice giving anesthesia. We cannot get our interns to take enough interest in anesthesia to do it right. We must hire somebody who will stay in the hospital one or two years and give anesthetics alone.

Dr. J. C. Bloodgood, Baltimore: Anesthesia is the stepping-stone to surgery; every surgeon who operates should have had experience in anesthesia. There is no practical experience which teaches the individual the physiology and the problems of physiology which are of the utmost importance to the surgeon in the treatment of respiration better than anesthesia. I think that men who go into surgery should have their experience of anesthesia, and that the anesthesia in most of the clinics where it is possible should be given by the men who ultimately expect to go into surgery.

What Can be Done to Preserve the Strength of the Patient During His Stay in Bed?

Dr. John M. Baldy, Philadelphia: Surgical patients, as a rule, are not sick in the sense, for instance, of a typhoid patient. Therefore, there is little call for efforts for sustaining strength after operation. The effort to force the appetite by drugs only prolongs the loss for an indefinite period. The excretory organs should be got to working actively by means of purgatives and diuretics. With a few exceptions the diet should not be limited, except as to quantity. A patient kept in bed two to four weeks on three full meals a day inevitably suffers from one or two attacks of indigestion. If the surgeon will use good judgment in deciding that an operation is desirable, will prepare his patient well, do his operation properly and pick his nurse carefully, he need not bother much about the after-treatment.

Transfusion

Drs. George M. Dorrance and Nathaniel Ginsburg, Philadelphia: In concealed bleeding within the abdomen or pelvis we frequently wait for the resultant syncope to arrest the bleeding. This too often results in loss of life. Instead of waiting and trusting to uncertainty we advise and practice transfusion. In this way it is possible to render cases apparently inoperable, on account of shock, suitable for operation. Instances of this are met with in gastric or duodenal hemorrhage, in hemorrhage following operation or typhoid or extra-uterine pregnancy.

Commission on Prevention of Venereal Diseases

Dr. Edward Martin, Philadelphia, chairman of this commission, offered on behalf of the commission recommendations that a medical certificate of freedom from veneral or other contagious diseases should be required from the man who contemplates marriage, that one who conveys venereal disease should be punished by a jail sentence, and that provision should be made for foci of infection so that the public may be protected.

The recommendations were adopted by the society and the commission was continued for another year with the same personnel.

Commission on Fractures of the Femur

Dr. William L. Estes, South Bethlehem, chairman of this commission, offered on behalf of the commission recommendations that teachers of surgery should give far more attention to the investigation of fractures and to the teaching of this important branch to their students; that while recognizing the fact that roentgenograms may be most misleading, they will, when properly made, furnish an indication for the proper reduction and preservation of apposition of the parts and serve as a graphic record of the fracture itself; that, while treatment by means of traction enables the patient in most cases to resume his occupation without serious detriment, yet roentgenograms show that absolute apposition and restoration of the proper axis of the bone are seldom accomplished; that the open method of treatment introduces such a very marked element of danger that the commission cannot recommend it for general use or recognize it as a routine practice, but that in selected cases it may be employed by an experienced surgeon; that some form of traction, such as Buck's extension, seems to be the preferable method of treatment, though Bardenheuer's transverse traction and Hamilton's apposition splints will serve a useful purpose in the majority of cases; that the usual methods of measurement are very inaccurate, though good functional results are obtained when the shortening is not over an inch, providing there is no inversion or eversion of the foot; that the usual method of measuring should be checked by measuring from the tip of the ensiform cartilage to the internal malleolus or the patella or from the middle of the umbilicus to the internal malleolus; and that in making measurements the pelvis should not be tilted and that the anterior spine should be in the same horizontal plane.

Commission on Cancer

Dr. J. M. Wainwright, Scranton, chairman of this commission, reported on behalf of the commission that county societies have been urged to devote meetings to the study of cancer and that a number have done so; that six short articles adapted to the lay reader have been prepared, and that these will be sent to all the leading newspapers in the state for publication; that from a report of 382 cases of cancer it was shown that only 68 per cent. of superficial cancers and 48 per cent. of deep-seated cancers were operable when they came to the surgeon; that in 39 per cent. of the superficial and 46 per cent. of the deep-seated cancers there had been a precancerous condition or a chronic irritation; that both the patient and physician are to blame for the delay in treating cancer, but that it would seem that the medical profession should be the first to show improvement in this respect.

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF POST-GRADUATE WORK, CONTRACT PRACTICE, LEGISLATION, MEDICAL DEFENSE, AND OTHER MEDICOLEGAL AND ECONOMIC QUESTIONS OF INTEREST TO PHYSICIANS

WOMEN'S CLUBS FOR BETTER HEALTH

The Public Health Department of the General Federation of Women's Clubs has taken up the systematic study of community health, as one of the regular features of club work. A special circular on this subject has been sent out to all women's clubs by the chairmen of the Public Health Department. This circular contains a program for women's clubs to follow in studying public health questions. It also appears in a recent number of the *Federation Bulletin.*

The significance and value of this campaign on the part of the federation cannot easily be overestimated. Women, as wives and mothers, are forced to bear the heaviest personal burdens that result from sickness in the household. If the women of the country will unite in a vigorous and persistent demand for better public health, they can wield an enormous influence in securing better conditions and in reducing the unnecessary sacrifice of life, now going on.

The attention of physicians is called to this mportant work. It is pecially of interest to e members of state d county committees legislation and pub- instruction. Every possible assistance should be given to the women's clubs in this work. In many cities, physicians can be of great assistance by co-operating with the public health committee of the local club, helping to arrange public meetings, to furnish speakers and to enlist the support of their friends and patients. Copies of this circular and program, as well as information regarding the work among women's clubs can be secured by addressing Mrs. S. S. Crockett, Chairman; Public Health Department; General Federation of Women's Clubs, Nashville, Tenn.

AMERICAN MEDICAL ASSOCIATION PRIZE CARTOON SERIES
C. Batchelor

IT IS INFINITELY MORE HUMANE, THAT A FEW ANIMALS DIE IN SCIENTIFIC RESEARCH, WITH LITTLE OR NO PAIN, THAN THAT THOUSANDS OF LITTLE CHILDREN SHOULD LIE ON BEDS OF PAIN AND PERHAPS, AT LAST, DIE IN AGONY.

SELECTED TOPICS FOR MONTHLY HEALTH CAMPAIGNS AND CLUB PROGRAMS, 1911-1912

October. Community Health

1. What is meant by community health?
2. What should be done to further the health of a community—(a) In homes; (b) in schools; (c) in factories; in shops; in offices; (d) in streets and alleys; (e) in markets; (f) in the drainage system and disposal of other wastes; (g) in provision of clean air and water.
3. What organizations and other agencies are helping to better the health of our community?
4. What can our club do to further these activities?

November. Social Hygiene

1. What is social hygiene?
2. What parents can do.
3. How mothers can teach.
4. What should be taught in primary schools; what should be taught in secondary schools.
5. Local reports. Has your board of education, has your superintendent, has any individual teacher taken any steps in regard to this subject?
6. What the club can do.

December. Ventilation

1. Why we should ventilate.
2. How to secure ventilation—(a) in homes; (b) in public buildings and conveyances.
3. Reports on local conditions—(a) in homes; (b) in schools; (c) in stores; (d) in factories; (e) in churches; (f) in theaters; (g) in public conveyances.
4. What this club can do about it. (a) Each individual member set a good example by ventilating her own home; (b) arrange lectures before local clubs; (c) print ventilation epigrams on your stationery; (d) agitate against specific local air polluters; (e) in public buildings (and conveyances) already constructed demand the best ventilation possible under existing conditions; where new public buildings are being erected interest architects and builders in installing up-to-date methods.

January. Mouth Hygiene—Teeth Inspection

1. What is oral or mouth hygiene?
2. The relation of the teeth to health; on teeth examination of school children in this community.
3. Reports: On education of children or adults regarding the care of the teeth; are there facts available concerning the condition of the teeth of school children of this community? have the local dentists planned to help this movement?
4. Talk by a local dentist on "How to care for the teeth," with a child to illustrate.
5. Discussion — "What can we do about it?"
6. Committee appointments—plans for doing something.

February. Clean Food

1. Definition—clean vs. pure food.
2. Reading from Mrs. Richards in proceedings of Boston biennial.
3. Requirements for clean lists—sanitary score cards.
4. Local accounts of successful food inspection work.

March. School Hygiene—Medical Inspection—School Nurse

1. What is medical inspection?
2. Review of Gulick and Ayers' book.
3. Beginnings — volunteer work.
4. Follow-up work—the nurse; the teacher; the home.
5. Reports of local conditions—from doctors; from teachers; from nurses; from mothers.
6. Where medical inspection is in vogue in this state—results, if any.

April. Conservation of Vision

1. Prevention of infantile blindness—(a) The cause; (b) how it may be prevented; (1) legislation; press; (2) by education; exhibitions; lectures.
2. Lecture by non-commercial electric engineer on "Prevention of eye-strain by proper lighting—in shops; in offices; in homes; in schools."
3. Local oculist discusses "Prevention of eye-strain by suitable glasses."

Chairman closes the meeting by laying special stress on broad conservation viewpoint in this particular question. Distributes literature furnished by the American Association for the Conservation of Vision, and mentions the conservation of vision day which the association proposes to promulgate in 1913.

May. Infant Mortality

1. The relation of vital statistics to infant mortality.
2. What are the chief causes of infant mortality?
3. How to interest and educate mothers.
4. What every mother ought to know.
5. Reports of local milk-supply.
6. Reports on local institutions.

N. B.—Definitions, suggestions and reference lists prepared by the section chairmen of the health department will appear in each succeeding number of the *Federation Bulletin* (Cannon Place, Troy, N. Y.).

It is respectfully suggested to clubs that, aside from the use of topics as programs for actual meetings, they may also be used for planning meetings elsewere, particularly in trying to get other bodies to use topics, and also for individual study and planning by any interested club women, and also for general suggestion to even the reader who may have but incidental interest, but who may look over the outlines in the club organs.

COMMUNITY HEALTH

Wherever homes are grouped, there exists one supreme common interest—the promotion of the public health. On this depends the happiness and efficiency of the individual, the family and society.

The requisites for public or community health may be loosely enumerated as follows: Clean air, water, food, clean homes, schools, churches, theaters, factories, shops, offices, conveyances, streets and alleys and clean citizens. Cleanliness means absence of filth, whose presence implies disease germs. Transmissible diseases have their origin in filth and are conveyed to an unsuspecting public in buildings, streets and conveyances as well as by water, food and milk. Add to this the part played by flies, mosquitoes and other insects.

The public health movement is coincident with the growth of the science of bacteriology, which makes possible the prevention of most diseases which were wont to have been considered inevitable. This includes the potential elimination of yellow fever and malaria, small-pox, the plague, leprosy, hookworm, typhoid, tuberculosis and all diarrheal diseases; has made possible aseptic surgery and midwifery, and a negligible mortality from diphtheria. The universal acceptance and observance of hygienic principles by the people is the object of the movement.

"A knowledge of danger is the surest way of guarding against it," and this knowledge of the immense effect on the common welfare produced by the destruction of germs before they reach the human body places a vast responsibility on public officials and public-spirited citizens and gives a new meaning to the phrase, "Am I my brother's keeper?" The responsibility for the application of sanitary methods rests on all who constitute that intangible but powerful agency called public opinion, for it is a well-accepted principle that what the majority of people want that will they get.

The fact that certain of our friends are made uneasy by so much talk of disease prevention should not give practical workers for improved health conditions cause for worry—"for the knowledge that certain diseases exist, that they have well-known causes, that they are disseminated by well-understood agents, and that their spread can be prevented by well-tried methods should make for peace of mind, not for worry." And it should be remembered that germs (and the filth-borne diseases) are no respecters of psychologic antagonisms, attacking alike the believer and the disbeliever. And while mental therapeutics is a valuable factor in the treatment of diseases of the nervous system, yet "think health—talk health"—"forget disease" is inapplicable to the germ and its extermination.

The eye of the sanitary world to-day is centered on Dr. W. C. Gorgas, whose work has made possible the construction of the Panama Canal, preceded as he was by Reed, Carroll, Lazear and others who proved the mosquito a carrier of yellow fever and malaria.

Of the agencies, official and voluntary, which are concerned in preventing disease and making life more productive, the first in present interest is the hoped-for National Department of Health which the General Federation endorsed at the Cincinnati biennial.

The object of a national health department is to investigate the causes of disease in general, to collect and disseminate such information, and to coordinate the various governmental agencies affecting public health into one department with an expert at its head.

Such a department would spread throughout the country such authoritative information on the conservation of human beings as the Department of Agriculture now does in the case of cattle. The government might make maps, as it now does to show the "beet belt," for example, showing in Dr. Wiley's words, "where the cancer belt is, where the greatest tuberculosis area is, where the typhoid area lies, what [illegible] nen and women of the finest physiques. S[illegible] be of illimitable value to the nation in a [illegible] t the reduction of disease, and would save [illegible] e nation now lost by unnecessary sickness and premature death." Of course, a national Department of Health could have no more to do with the individual practice of medicine than the Department of Agriculture has to do with the individual management of a farm. The Constitution of the United States makes this impossible in any of the states.

Those who oppose federal aid in health matters (the most important that could concern a nation), claiming that it will further the interests of any school or cult, fail to catch the real object of the department, which is to "prevent" disease, and concerns itself not at all with any method of treatment.

Perfected federal, state, county and municipal aid and control of health problems is a consummation not only to be wished but worked for, and the obligation of women's clubs, as homemakers and mothers in such efforts, would seem to be clearly defined, for women's clubs have emerged from the self-culture period and reached the stage where they work not only for the welfare of their own homes and children, but "for women other than themselves, for children other than their own."

The only possible discussion of the question revolves around the point of ways and means.

In connection with monthly health programs, submitted for your consideration, as applicable to actual club or committee meetings, your chairman offers the following general suggestions:

CLUBS OR COMMITTEES

1. Should seek to inform themselves about what needs doing, the best way of doing it and the proper organization or department to do it.
2. Should become a center of inspiration in the community and create a "health consciousness."
3. Should seek to spread a knowledge of the best methods among those doing health work.
4. Should plan systematically to get other organizations interested to the end that each take up a particular community need.

Thus the club becomes a coordinating power and helps to form an orderly social program, each in its own community. By cooperating with corresponding national organizers this desirable goal may be reached for the whole United States.

HEALTH DEPARTMENT PROGRAM

The public health department of the General Federation of Women's Clubs asks that all federated clubs unite in a common month-by-month campaign of study and work, and invites all other public-spirited women's organizations to join in the same cooperative movement. The chairman, Mrs. S. S. Crocket, from the headquarters at Nashville, Tenn., announces nine topics for study and "talk," and nine "campaigns of education," to be handled as follows: October, Community Health: "Know Your City" campaign; November, Social Hygiene: Sex Education in Home and School; December, Tuberculosis: Ventilation and Fresh Air; January, Mouth Hygiene: Tooth Inspection Day; February, Clean Food: How and Where to Get It; March, School Hygiene: Medical Inspection; April, Conservation of Vision: Prevention of Blindness; May, Infant Mortality: "Don't Kill Your Baby"; June, Food Sanitation: Needless Summer Dangers.

The entire health machinery of the American Federation of Clubs and thousands of local clubs will be centered on this program of study, "talk" and real work, with new plans and original ideas to be announced from month to month.

POSTGRADUATE COURSE FOR COUNTY SOCIETIES

[Note.—The pamphlets containing the outline of the postgraduate study course for county societies for the coming year are ready for distribution. Secretaries of county societies can secure supplies by writing to the Secretary, Council on Health and Public Instruction, American Medical Association, 535 Dearborn Ave., Chicago.]

General Subject for the Month: Rheumatism and Gout

Third Month—First Weekly Meeting

ANATOMY

ARTICULAR STRUCTURES: Articular lamella of bone. Articular cartilages. Interarticular fibro-cartilages. Synovial membrane, structure, attachments, secretion, synovial ligaments.

PERI-ARTICULAR STRUCTURES: Ligaments, structure, attachments. Muscles and tendons, tendon sheaths. Nerves and blood-vessels.

ENDOCARDIUM: Origin, structure, thickness, reduplications, aortic valves, mitral valves.

ETIOLOGY OF ACUTE RHEUMATISM[1]

PREDISPOSING CAUSES: Heredity. Age. Sex. Occupation. Climate, season and locality. Diet. Epidemics. Chronic endocarditis and chorea.

FACTS INDICATING THAT RHEUMATIC FEVER IS AN ACUTE INFECTIOUS DISEASE: Incidence, clinical features, bacteriology. "*Micrococcus rheumaticus*."[2] staining and cultural characteristics. Other organisms suggested.

OLD THEORIES OF RHEUMATISM: Metabolic (Prout, Latham), and nervous theory (Mitchell).

REFERENCE BOOKS FOR THE THIRD MONTH

The following text-books on practice: Osler, Tyson, Hare, Anders, Edwards, Strümpell. The following on gout: Duckworth, Ewart, Luff.

Osler's Modern Medicine.
Allbutt's System of Medicine.
Symes: Rheumatic Diseases.

Heredity.—"Heredity," says Ribot, "is that biological law by which all beings tend to repeat themselves in their descendants; it is for the species what personal identity is for the individual. By it a groundwork remains unchanged amid incessant variations; by it Nature ever copies and imitates herself."

Medical Education and State Boards of Registration

COMING EXAMINATIONS

ARKANSAS: Regular, Little Rock, November 14. Sec., Dr. F. T. Murphy, Brinkley; Homeopathic, Little Rock, November 14. Sec., Dr. P. C. Williams, Texarkana.

CONNECTICUT: Regular, City Hall, New Haven, November 14. Sec., Dr. Charles A. Tuttle, 196 York Street; Homeopathic, Grace Hospital, New Haven, November 14. Sec., Dr. Edwin C. M. Hall, New Haven; Eclectic, Hotel Garde, New Haven, November 14. Sec., Dr. Thomas S. Hodge, 19 Main Street, Torrington.

FLORIDA: Regular, Jacksonville, November 7-8. Sec., Dr. J. D. Fernandez.

LOUISIANA: Homeopathic, New Orleans, November 13. Sec., Dr. J. T. Crebbin, 1207 Maison Blanche Building.

MAINE: City Council Rooms, Portland, November 14-15. Sec., Dr. F. W. Searle, 776 Congress Street.

MASSACHUSETTS: State House, Boston, November 14-16. Sec., Dr. Edwin B. Harvey.

NEVADA: Carson City, November 6. Sec., Dr. S. L Lee.

TEXAS: Fort Worth, November 14-16 (change of date from previous notification). Sec., Dr. J. D. Mitchell.

WEST VIRGINIA: Hotel Waldo, Clarksburg, November 13-15. Sec., Dr. H. A. Barbee, Point Pleasant.

Massachusetts September Report

Dr. Edwin B. Harvey, secretary of the Massachusetts Board of Registration in Medicine, reports the oral, practical and written examination held at the State House, Boston, September 12-14, 1911. The number of subjects examined in was 13; total number of questions asked, 70; percentage required to pass, 75. The total number of candidates examined was 61, of whom 40 passed, including 3 osteopaths, and 21 failed, including 4 osteopaths and 3 non-graduates.

Mississippi October Report

Dr. S. H. McLean, secretary of the Mississippi State Board of Health, reports the written examination held at Jackson, October 9-10, 1911. The number of subjects examined in was 8; total number of questions asked, 64; percentage required to pass, 75. The total number of candidates examined was 90, of whom 27 passed, including 12 non-graduates and 1 osteopath, and 63 failed, including 26 non-graduates and 1 osteopath. The following colleges were represented:

Book Notices

A TEXT-BOOK OF MEDICINE. By G. Dieulafoy, Professor of Clinical Medicine at the Faculté de médecine de Paris. Authorized English Translation from the Fifteenth Edition of "Manuel de pathologie interne" by V. E. Collins, M.D., M.R.C.S., L.R.C.P., and J. A. Liebmann, Ph.D., M.A., LL.D In two volumes. Volumes I and II. Cloth. Price, $12. Pp. 2081, with 105 illustrations. New York: D. Appleton & Co, 1911.

The English translation of this popular French treatise will be welcomed by English-speaking physicians. The fact that fifteen editions of the book have appeared in the original language is sufficient evidence that it is fulfilling the purpose of a work on practice by a single author. Dieulafoy has adopted a simple classification of diseases of the different systems and writes from his personal experience rather than in a didactic text-book manner, frequently giving hypothetical or actual cases to illustrate a disease or a method of handling and treatment. This is a satisfactory and comforting method to the physician who turns to a text-book for information on the management of his cases. The author gives no prescriptions but suggests drugs and measures, outlining as far as possible a complete scheme of treatment and management in the various affections. The work has numerous charts, cuts and colored plates illustrating the pathology. The English edition is in two volumes and mechanically is well rendered.

OPHTHALMIC MYOLOGY. A Systematic Treatise on the Ocular Muscles. By G. C. Savage, M.D., Professor of Ophthalmology (Defects of the Eye) in the Medical Department of Vanderbilt University. Second Edition. Price, $4. Pp. 685, with 84 illustrations. G. C. Savage, 137 Eighth Avenue, Nashville, Tenn., 1911.

This well-known work on the extrinsic and intrinsic muscles of the eye having reached a second edition, has been considerably enlarged by the addition of ninety-one pages to the first chapter and the insertion of twenty-three new cuts. Moreover, the practical chapters, 2 and 12, have had such corrections and additions made to them as seemed to be necessary to elucidate the theorems and hypotheses which the author set forth in his first book. These comprise the fundamental principles of ocular rotations and include chapters on orthophoria, heterophoria, esophoria, exophoria and cyclophoria. The attention of the reader is called to the chapters on the paralyses and pareses of the ocular muscles, and to the following chapter which in an original manner discusses the muscles of the iris and of the ciliary body, particularly in their relations to accommodation, convergence and other normal and abnormal movements of one or both eye-balls.

A MEDICAL HISTORY OF THE STATE OF INDIANA. By G. W. H. Kemper, M.D. Cloth. Price, $2.50. Pp. 393, with illustrations. Published by the Author, Muncie, Ind.

This volume contains the articles which the author contributed to the *Journal of the Indiana State Medical Association* during 1909-1911 while he was chairman of the committee on necrology. There is an interesting introduction by Dr. Brayton of Indianapolis. The chapters on the early medical history of Vincennes and Indiana are full of valuable historical material, as are the succeeding chapters dealing with the early history of various localities. There are chapters on the state society, on epidemics and health laws, war history, and an alphabetical list of deceased physicians, together with biographical notices in a number of instances. Pictures of a number of the more prominent physicians are inserted. As a source for reliable historical material, Dr. Kemper's book will acquire an increasing value as years go on. The example he has set for state medical history should be followed in other states.

Medicolegal

Medical Practice Act Not Invalid in Not Providing for Licensing Masseurs—Admissible Evidence of Violation of Law—Who Amenable to Law

(Germany vs. State (Tex.), 137 S. W. R. 130)

The Court of Criminal Appeals of Texas again affirms a judgment against a masseur for practicing medicine and treating disease without registering a certificate as required by law. The court says that it was contended that the law regulating the practice of medicine was unconstitutional, and that there was error in a refusal to permit the defendant (Germany) to show that "there was no board of medical examiners nor any authority in the state of Texas to whom he could apply for a license or permit to practice massage treatment, and that, as the law made no provision for the practice of masseur treatment, it was discriminating in its character." But the court knows of no higher duty a government has than to protect the life and health of its citizens and, if experience has shown that no man should be permitted to treat disease who has not a knowledge of the subjects named in the medical practice act, the legislature not only had the power, but it was its duty, to pass a law protecting the citizens of the state.

The law does not attempt to say how any one shall treat disease. This is left to the sound judgment of the practitioner. All it says is that he must have a knowledge of certain given subjects before he shall undertake to practice. If the defendant desires to treat those who are sick, let him demonstrate he has a knowledge of the subjects named in the law, and he can treat disease in the manner that is by him deemed best. Physicians all state that in some character of diseases they use "massage," and that it is beneficial, while in others it is harmful.

The court did not err in not permitting the defendant to prove there was no board where he could obtain license to practice massage. There is a board where he can obtain such a license; but he must show, in order to get that license, that he has a knowledge of the human anatomy, is able to diagnose disease, and has a knowledge of the studies named. This is a wise provision, as this court sees it. In protecting the liberty of the citizen, and in protecting him in his property rights, our laws provide that no man shall practice law, or appear in the courts in behalf of another for a remuneration, unless he has gone before a board and demonstrated he has a knowledge of certain principles underlying the law, naming certain books he must read and master to some extent at least. When we are thus careful in dealing with the liberty and property of our citizens, how much more care should we take when we come to deal with matters relating to his very life and the preservation of his health.

Nor was it error to permit the state to prove that the defendant had treated others than a certain Miss Luther, the offense with which he was charged being that he was offering to treat disease for pay without having registered his certificate. An advertisement issued by him and the fact that he treated others for disease contemporaneously with Miss Luther were all admissible, as was the fact that he told Mr. Luther he could cure his daughter of appendicitis.

It was not a question in the case whether the treatment given by the defendant was harmful or beneficial, and the court did not err in not permitting that issue to get in the case.

It was also immaterial whether Miss Luther had been treated by others before she was treated by the defendant; but the fact that the court permitted her father to state that he had his daughter treated by other physicians before she was treated by the defendant could not be injurious to the defendant.

The fact that the defendant represented to witnesses that he could cure certain diseases, and had cured them, was also admissible. Any statement of a defendant relative to the offense for which he is being tried can be proven if the state desires to elicit it.

As the defendant was claiming that he was exempt under the provisions of the medical practice act, it was proper to admit the testimony of physicians as to being familiar with the sphere of labor of a masseur, such as is exempted under the operation of the medical practice act, and that the sphere is to work under the directions of a physician; that one who is not well up on anatomy, physical diagnosis, etc., is not capable of directing the use of massage.

Under the repeated decisions of this court, one who shall treat or offer to treat mental or physical disease by any system or method, and charge therefor, and who has not obtained authority to do so from the medical board, is amenable to the law.

Evidence of Negligence in Failure to Attend Case as Promised

(Adams vs. Henry (Mich.), 131 N. W. R. 62)

The Supreme Court of Michigan reverses a judgment directed for the defendant in this action for malpractice. The plaintiff claimed that premature labor had been brought on by a jar while alighting from a street car, and that the defendant, who had called on her several times in the afternoon promised to return promptly at 11 o'clock, maybe a little earlier, but did not return until 2 o'clock a. m., while the child was born at five minutes after 12 a. m. The plaintiff also offered to prove that her husband had shortly after 11 o'clock called the defendant by telephone, also a little later, and again after the child was born, and that the defendant had each time promised to attend at once, but did not until the time stated. The court holds that if the plaintiff had been permitted to produce, and had been able to produce, testimony tending to establish the statements contained in the offer of proof, it could not be said as a matter of law that the defendant was not negligent. If the defendant was present and responded personally to each call that was said to have been made on him between 11 and 12:30 o'clock, and on each occasion agreed to at once attend the plaintiff and failed to keep his promise, the court thinks he should be held liable, if his failure to attend resulted in injury to the plaintiff. The plaintiff's declaration contained the averment that a laceration of the cervix and rupture of the perineum resulted from the defendant's failure to attend as it was alleged that he had agreed to do, and the court is disposed to the view that the plaintiff should have been permitted to offer such testimony as she possessed pertinent to the issue.

Current Medical Literature

AMERICAN

Titles marked with an asterisk (*) are abstracted below.

11 *Physiologic Conception of Arthritis and Some of Its Practical Uses. H. W. Marshall, Boston.

1, 2, 3, 5, 7, 8 and 9. Abstracted in The Journal, June 17, 1911, pp. 1845 and 1846.

4. **Tuberculin in Orthopedic Diagnosis.**—In 471 cases Stern has used the following "combined" test: When a case presents clinical signs pointing to the possibility of a tuberculous infection, a v. Pirquet and a Calmette test are made at the same sitting. The patient is seen at the end of twenty-

four and again after forty-eight hours. If both tests are positive the case is held to be one having an active tuberculosis; if both tests are negative the case is declared free from tuberculosis. Where one test is positive, and the other negative (it usually falls out v. Pirquet positive, Calmette negative), the subcutaneous or intracutaneous prick reaction is resorted to. The smallest possible doses are given subcutaneously, since there is already one negative test and it is desired only to bring out evidences of active tuberculosis. If the third test proves positive, active tuberculosis is diagnosed, and vice versa. Wherever possible the findings have been checked up by laboratory examinations of scrapings, pus, cerebrospinal fluid, etc., Roentgen-ray examinations, autopsy (one case), the clinical course of the disease, and by the variation of the opsonic index after massage and passive motion. In all, Stern knows of but six cases out of the 471 tested in which a mistaken diagnosis was made and in all of these the error was a positive one, i. e., tuberculosis was indicated where it did not exist; but in no case was a tuberculous infection overlooked. In two out of the six a Wassermann reaction done at other hands proved positive and the patients improved under antisyphilitic treatment. The other four cases were all mild cases of arthritis, clinically suspicious, in whom the Roentgen ray gave the clew to the proper diagnosis; none ran the course of a tuberculosis. None of the cases so severe as to give a chance for laboratory investigation was mistaken. Two patients who died from tuberculous meningitis within fourteen days after Stern first saw them, one a tuberculous coxitis, the other a tuberculous shoulder and hip case, gave positive reactions.

6. **Anterior Heel.**—The anterior heel advocated by Cook is an inverted isosceles triangle prism of leather, the base being about 2 inches and the altitude varying from 2/16 to 5/16 of an inch. This prism is placed obliquely across the bottom of the shoe, the vertex of the triangle being just behind the anterior arch or ridge formed by the heads of the metatarsal bones. The base of the triangle is applied to the inner sole, the outer sole following the contour of the two equal sides. The shoe is provided with a heavy steel shank which is supported behind by a low, broad heel, and in front by the anterior heel. The anterior heel, when studied in connection with the steel shank and the posterior heel, is an important element in the balance of the shoe, and by the use of the anterior heel, the following facts are demonstrated: (1) The center of gravity of the body is moved backward and the pressure thus removed from the heads of the metatarsal bones. (2) By supporting the steel shank with the anterior heel, the posterior arch of the foot is supported, and the pressure distributed by increasing the bearing surface. (3) In the act of walking, when the weight passes from the heel and instep to the ball of the foot, the anterior heel acts as a fulcrum and thus relieves pressure on the heads of the metatarsal bones. (4) While standing on the balls of the feet, the anterior heel supports the heads of the metatarsal bones, equalizes pressure, and prevents the falling of the anterior arch. The anterior heel affords instantaneous and efficient relief from all troubles of the anterior part of the foot, whether considered singly or collectively, such as depression of the anterior arch, callosities, corns, bunions, twisted or distorted toes, Morton's toe, anterior metatarsalgia, etc., etc. The common cause of all these troubles is undue pressure, and the anterior heel, by removing this pressure, removes the cause, and places the injured parts in a position in which recovery is possible. A shoe balanced in this manner forms a reliable base for a simple "orange-peel" instep support. The shoe and instep support prevent no normal motion of the foot and impede no normal action of the muscles; a weak foot is not bound down and splinted, but is carefully balanced and supported and kept in a normal position. Walking is easy and natural, and when the weakened muscles have regained their power and the overstretched ligaments have contracted to their proper length, the arch of the foot rises above its support and the support becomes superfluous. Cook claims that shoes and instep supports made in this manner and worn indefinitely will in no way injure normal feet.

11. **Physiologic Conception of Arthritis.**—Marshall calls attention to the fact that knowledge of physiologic conditions which control the health of joints offers a rational means of simplifying and harmonizing the legion of confusing observations and theories. Nervous, infectious, metabolic, mechanical and anatomic theories all may be included in a physiologic conception which recognizes the possibility of influencing joints through their blood and nerve-supply, and by mechanical motions, and other physical agencies. Physiologic conceptions of joint disease include bacterial theories of arthritis, metabolic theories, also the action of drugs and food products in the single group of blood irritants. Excessive mechanical irritations, deformities resulting from continued mechanical strains, contractions and postures acquired during acute stages of arthritic diseases due to faulty attitudes while in bed, may be harmonized on a physiologic basis and interpreted as departures from normal physiologic functions through faulty mechanical and anatomic conditions. Nervous theories also are not overlooked, and the importance of nervous control of joints is emphasized. By supplementing this knowledge of physiologic conditions which control the health of joints with the physiologic conceptions of interactions between organs, and the variable resistances of tissues, an adequate hypothesis may be formulated which is simple enough to be remembered, and which satisfactorily explains all confusing observations and ideas that now exist.

If there have been recurring attacks of joint symptoms in a person who has always been in delicate health it is unreasonable to believe that arthritis will cease abruptly and permanently, and treatment in such cases first of all must be directed toward building up very slowly the general vigor and resistance. Cases with abrupt onset of arthritis in full health, with joint symptoms occurring for the first time, have different prognosis and treatment; and while it is impossible to predict the length and severity of symptoms in such instances, obviously remedial measures should not be prescribed, although they often are, with the same frequency and degree of vigor as used with delicate persons. When a period of failing health has preceded the onset of arthritic disease, as very frequently happens, personal habits and modes of living should receive particular attention; and generally the causes may be discovered in common, uninteresting defects in personal hygiene which, when corrected, are followed by subsidence of joint pains and stiffness and by return to usual health. It is Marshall's custom to inquire closely into the patient's daily routine, the time of arising, kind of breakfast eaten, the nature of the occupation, hours of work, and whether there is an excessive amount done; the midday meal and regularity in taking it; also the nature of the evening meal, and how evenings are generally spent; what the usual hours for sleep are, and whether it is restful or disturbed; the individual's usual recreations; the amount of out-door exercise; the appetite, peculiarities in diet, and regularity of intestinal functions; the existence of mental worries and habits of taking stimulants. The patients' opinions of their own condition and what caused the failing health are asked; and from these simple questions it is possible to gain very accurate ideas of the daily life and often to discover remediable defects which alone are responsible for poor health and arthritis. Cases of intractable arthritis must have their beginnings in these same simple, commonplace defects of personal habits that escape recognition owing to their simplicity and ordinary character; and if this is true it indicates that early treatment and prevention of joint disease is the most important and rational course to advocate.

22 *Pellagra, with Its Peculiarities on the Plains. E. H. Inmon, Takoka, Texas.

19. **Latero-Lateral Anastomosis of Ileum and Sigmoid Flexure.**—It is claimed by Noble that this operation will cure mucous colitis in properly selected cases. Patients with atonic dilatation of stomach and absence of free hydrochloric acid are not good subjects for it and if it be done in this class of patients, persistent treatment subsequently for diseases of the stomach should be enforced. All contributing causes to constipation that can be relieved by surgical measure, should have attention at the time the anastomosis is made. A large percentage (75 per cent.) of Noble's twenty-seven patients received prompt relief from the operation, others required from one to two years to effect a cure, while a small per cent. are but little improved. He cautions that it is not to be depended on as a cure to the exclusion of diet, exercise, and in some instances, laxatives. Partial diversion of the intestinal current into the rectum does not cause diarrhea but on the other hand absorption of fluids by the rectum causes "drying out" of feces, and more or less constipation in about 25 per cent. The patients are cured of mucous colitis though not entirely relieved of constipation. It does not interfere with nutrition. The absorption of toxins is diminished, but absorption of water is ample. The operation is based on the principle that mucous colitis is largely caused by constipation and putrefactive decomposition. From this point of view, the direct object of the anastomosis is to partially drain the most intensely affected section of the ileum, preventing its full discharge into the cecum; for the amount of decomposition, irritation and absorption of toxins is more or less in proportion to the quantity of proteins and degree of stasis in the colon. In the technic of the operation, the suture method is preferred and the anastomosis made as low down on the ileum and sigmoid as the two portions of the intestinal canal can be approximated without tension. Loops are drawn out of the abdomen far enough to make the work easy and to avoid angling of the bowel. The danger of infection is minimized by the use of the rubber dam. This is a piece of rubber sheeting about 14 inches square, in which two slits are cut about 1½ inches long and 6 inches apart, through which the knuckles of the intestines are drawn. The rubber is grasped between the thumbs and fingers of both hands and slightly stretched as each loop of intestine is placed in the clamp. None of the intestine except the immediate portion involved in suturing is exposed to infection from opening the lumen of the canal. After the raw edges are sutured, the exposed parts are thoroughly cleansed and clamps and rubber dam removed. The operation is completed aseptically.

21. **Noguchi Modification of Wassermann Reaction.**—A typical lesion in which spirochetes had previously been found, gave Black a positive reaction after seven weeks. The eruption soon followed. Four weeks after the appearance of a chancre on the lip, a positive reaction was found. These are the earliest positive reactions he has obtained. Two suspicious lesions, each of six weeks' duration, gave negative reactions and later healed without treatment and no secondaries occurred. A suspicious ulcer of the tonsil gave a negative reaction and healed promptly under local treatment. Of seven patients showing typical syphilitic eruptions, all were positive. Eleven cases in the tertiary stage, showing active symptoms, all gave positive reactions. Of nine patients who gave positive histories, but who have had no symptoms for periods varying from a few months to several years, seven gave negative reactions. Three cases with suspicious but not positive histories and showing no definite symptoms, gave negative reactions. Of sixteen cases giving a negative history and yet showing suspicious lesions, fifteen were negative and one positive. This positive case later responded to salvarsan. One of the cases giving a negative reaction is seen now to be clinically syphilis and is responding to the exhibition of mercury. This is the only failure of the reaction in this series. Black has made only six examinations of patients who had previously given positive reactions and had been given an intramuscular injection of salvarsan. These second examinations were made from six to eight weeks after the injection and were all negative. One of these cases after salvarsan, two months after his previous reaction, remains negative. One case of congenital syphilis was positive and one patient showing some obscure mental disturbance also responded. The latter gave a history of fifteen years' standing.

22. **Pellagra.**—The peculiarities of this disease on the plains seems to be that the disease is much more severe than in the lower altitudes of Texas. The cases which have been observed by Inmon presented all the usual symptoms, except one case, in which the patient's mind was not affected to within ten hours of death. As a rule, pellagra on the plains runs a short course and very promptly terminates in death.

28 *Transplantation of Free Flaps of Fascia. J. S. Davis, Baltimore.

25. **Infection of Urinary Tract by Bacillus Lactis Aerogenes.**—Luetscher summarizes his conclusions as follows: The *B. lactis aerogenes* is a rare cause of cystitis. The great majority of infections are due indirectly to the introduction of instruments. Infections of the bladder, in cases in which no instruments have been introduced, are very frequent in women and rare in men. In infections of the bladder in women, without a history of the introduction of instruments, the route of infection is usually an ascending one and due to the direct invasion of the bacteria from the urethra. Such direct invasion of the bladder also occurs in the male and probably much more frequently than is usually supposed. The introduction of a catheter or instruments into the bladder is a very serious procedure, since it may produce a pyuria if the local conditions are favorable, or a bacteriuria which later may be converted into a pyuria when the local conditions become favorable.

27. **Blood-Picture in Hodgkin's Disease.**—One of the most marked characteristics of the blood-smears of Hodgkin's disease, according to Bunting, is the presence of a large number of blood-platelets, inclusive of unusually large platelet forms, practically megalokaryocyte pseudopodia. This was observed in all the eleven cases forming the basis of this report, both in early and in late cases, and over considerable periods of time in cases in which blood-counts have been made at intervals. From this constant finding and from pathologic findings in autopsy material from cases of Hodgkin's disease, it was suggested in a previous report that the toxin of the disease acted as strongly on the platelet-forming elements as on the lymphocytes. An eventual necrosis of megalokaryocytes in the bone-marrow was found. One case of the present series, showed a low platelet-count in the circulation. After having shown a high platelet content of his blood in counts at intervals from Nov. 9, 1909, to September, 1910, the boy returned to the hospital in April, 1911, with serious hemorrhages from the mucous membranes, with a secondary anemia, a leukopenia, 3,500 to 4,000, and fewer platelets than leukocytes, as shown by repeated examinations made during April and May. However, while exceptional or terminal cases may show this platelet exhaustion, the excessive number would appear to be constant in the course of the disease. Coincident with this platelet study, careful study of the leukocyte picture in the disease has been made and has led to the conclusion that in the combined platelet and leukocyte picture one has features that are very characteristic and, in fact, almost pathognomonic of Hodgkin's disease.

While from his experience Bunting believes that the diagnosis may be made from examination of the blood-smear, he would not recommend the method to the exclusion of the histologic examination of an excised gland. The blood-smears have been stained with Wright's stain for the purposes of the counts, although Ehrlich's triple stain has been used for the determination of certain features. Five hundred cells have been the routine and the smallest number counted, but in some cases this has been exceeded. The leukocytes have been grouped into seven classes, except in a few of the early counts wherein but six were made. These groups are: (1) Polymorphonuclear neutrophil (N.); (2) eosinophil (E.); (3) basophil (mastzell) (B.); (4) small lymphocyte (S. L.); (5) large lymphocyte (L. L.); (6) large mononuclear (L. M.); (7) transitional (Tr.). The most striking feature in the counts, perhaps, is the constant high percentage of the so-called transitional cells. This high percentage occurs not only when the total leukocyte count is approximately normal, but also is maintained even when there is a sharp leukocytosis. With a normal total count of leukocytes the percentage of transitionals approximates 10; with a very marked leukocytosis one may have a reduction (6.4 per cent.); while in a leukopenia the percentage rises to 17.8 in a total of 4,800. The series indicates, then, that throughout the disease there is a relatively large number of these cells in the circulation. When one recalls that similar cells are found in smears from normal lymph-glands and also that in Hodgkin's disease there is a marked proliferation of the endothelial elements of the glands, it is difficult not to draw the conclusion that such a proliferation results in this excessive transitional content of the blood. The lymphocyte-count has varied much in these cases, but there is a definite tendency for a percentage decrease from a normal or slightly increased count in early and active stages to a very low count in later stages. With this decrease in lymphocyte percentage, there occurs a corresponding *increase in the polymorphonuclear count, from a relatively normal count during the course of the disease, to a relatively high count* (76.2, 79.4, 81.8, 84 per cent.) in the terminal stages or when the periglandular infiltration and induration are marked. Eosinophils are found in the glands in large numbers. The highest count found was 8.6 per cent. There is no striking change in the basophil-count, or in that of the large mononuclears.

28. **Transplantation of Free Flaps of Fascia.**—In one group of experiments made by Davis, free fascia flaps were successfully transplanted into the subcutaneous tissue, into fat, on muscle, periosteum, bone, cartilage, tendons and ligaments. Microscopic examination of the specimens showed that the fascia retained its own structure after transplantation and was apparently healthy and well nourished. This was true even after the fascia had been kept in cold storage for thirty-five days and then transplanted into another animal. A second group shows that muscle and tendon defects may be bridged by three flaps of fascia. Muscle defects may be bridged by means of fascia flaps and thus a certain amount of the muscle function saved. The fascia united firmly with the muscle ends and formed a strong symmetrical band between them. A third group shows that free flaps of fascia may be transplanted successfully around arteries, veins and nerves, without in any way interfering with the lumen of the vessels, or compressing the nerves. In a fourth group free flaps of fascia were successfully transplanted into joints and also to take the place of patellæ which had been removed. A fifth group shows that flaps of fascia inserted in skull defects between the dura and bone edges will heal and give a strong membrane which will resist considerable pressure from within and without. When the dura is removed in addition to the bone the fascia flap tucked under the bone edges will unite with the dura and also become tightly adherent to the bone edges. There was in each instance a single fine adhesion of the cortex to the center of the fascia flap. This group also shows that free flaps of fascia may be successfully used to cover prepared defects in the trachea, without subsequent infection and that the mucous membrane grows across the fascia covering the defect. A sixth group shows that free flaps of fascia may be sutured into peritoneal and muscle fascia defects in the abdominal wall and that it will incorporate itself with the surrounding peritoneum and muscle edges. A small omental adhesion was present on examination of the specimen in each instance, but in no case was there adhesion of the gut or any other abdominal organ to the fascia. When a hernia was produced by the removal of a portion of the abdominal wall, except the skin, it was readily cured several weeks later by the transplantation of fascia flaps. In group six, *free fascia flaps were successfully transplanted onto the* stomach, the intestine and the bladder. The fascia seemed to incorporate itself with the peritoneum. In group seven free flaps of fascia were successfully transplanted on the liver, kidney and spleen.

In several experiments fascia was drawn taut and sutured around firm rubber tubes 0.8 to 1 cm. in diameter and then inserted in the subcutaneous tissue. These specimens were removed after forty-nine and fifty-four days. The structure of the fascia could easly be seen. Microscopic examination showed normal staining fascia with no signs of degeneration. This is interesting as it shows that fascia will receive sufficient nourishment if only one surface is exposed to living tissue. Once or twice the fascia flap was accidentally allowed to partially dry out before it was transplanted, but, in spite of this, it was moistened with salt solution and transplanted. The results were excellent and the fascia was nourished and grew in its new position.

49. **Buttermilk as Infant Food.**—Neff does not believe that buttermilk should be considered as a substitute for sweet milk in the feeding of healthy infants. His experiences prove that the cases for the feeding of buttermilk as for any other form of milk should be selected, and that the daily weight and other evidences of gaining should be closely watched. Buttermilk is more especially suited to sick infants, those with marasmus, chronic enterocolitis, exudative diathesis and those that are commonly termed difficult feeding cases. It may be given for a period of several months without causing unfavorable symptoms and top milk may be gradually added if desired. It is especially of value in the summer months, at which season it will be better tolerated and will produce

better stools than the same case would have done on a sweet milk mixture. Chilling and proper handling of a clean fresh milk is essential to the successful administration and good results in buttermilk feeding.

51. **Treatment of Pneumonia.**—Killian's treatment is entirely symptomatic. He says that to maintain life the careful management of the stomach by suitable diet to prevent distention and the consequent cardiac embarrassment is of the highest importance. To support the heart; the best drugs for this purpose are strychnin, caffein, alcohol, digitalis, camphor and adrenalin. Treat the symptoms as they arise; not the pneumonia, but the patient with pneumonia.

64. **Creatin and Creatinin Metabolism.**—Two fundamental facts are emphasized by the experiments of Mendel and Rose: (1) An increase in the elimination of total creatinin (i. e., creatin plus creatinin) is always accompanied by an increase in the output of total nitrogen; and (2) carbohydrates, in contrast to the other foodstuffs, are capable of preventing the excretion of creatin and are therefore indispensable for normal creatin-creatinin metabolism. They found that the excretion of creatin induced by starvation, is inhibited in rabbits by feeding a diet of carbohydrates absolutely free from proteins and fats. When the carbohydrates are given in liberal amounts, creatin entirely disappears from the urine. The creatin elimination is not reduced by feeding a diet of fat alone, or by a diet of fat and protein. Experimental interference with carbohydrate metabolism leads to the elimination of creatin. After phlorhizin diabetes which depletes the store of carbohydrates and during phosphorus poisoning, which disturbs the glycogenic functions, the output of creatin in dogs is decidedly increased. An increase in the output of creatin plus creatinin (total creatinin), is always accompanied by an increase in total nitrogen elimination. This parallelism of total creatinin and total nitrogen outputs in inanition and with nitrogen-free diets is ascribed to a common source, namely, true tissue or endogenous metabolism. The metabolism of exogenous or reserve proteins is not accompanied by the production of creatin or creatinin. The intimate relation of creatin excretion (or the failure of conversion into creatinin) to carbohydrate metabolism, is discussed in detail.

65. **Inanition and Creatin Content of Muscle.**—The authors are convinced that there occurs an increase in the percentage of creatin in the muscles of rabbits and fowl during inanition. Two possible explanations for the larger amount of creatin suggest themselves. The increase may be due (1) to a removal of the non-creatin portion of the muscle, leaving the creatin intact; or (2) to an increased formation of creatin. The first explanation seems improbable, for if the creatin is loosely combined with muscle as Urano ('07) believes, there is no reason for assuming that the non-creatin material could be withdrawn and leave the creatin intact, any more than for assuming that the reverse could occur. An increased formation seems to be the most plausible explanation.

66. **Excretion of Creatin in Infancy and Childhood.**—In view of the observations that creatin is a normal constituent of the urine of sucklings Rose attempted to determine the age at which this product disappeared. Thirty-nine specimens of urine from children of different ages were analyzed. With the exception of two cases, creatin was present in all specimens from children under 15 years of age. A boy of 10 and a girl of 13 failed to have creatin in their urines. No progressive decrease in the percentage of the total creatinin in the form of creatin coincident with increase in age is apparent; neither is the percentage of creatin constant for the same individual. For instance, one specimen obtained from a child of 5 years contained 24.2 per cent. of the total creatinin in the form of creatin, while a second sample from the same child a few days later, contained 79.2 per cent. of the total creatinin as creatin. It was impossible to obtain information as to the amount and kind of food eaten by the children. Most of the specimens were obtained from the city orphans home or from private families, and the subjects of the experiments were probably ingesting more or less meat. It is possible, therefore, that the oxidation or conversion of creatin into creatinin may be difficult for young individuals to accomplish and in this case the creatin of the urine may in part, represent ingested creatin; or the glycogenic functions may be imperfectly developed and the store of carbohydrates be insufficient to exert its regulatory influence over metabolism during childhood.

67. **Hydrazin and Pancreatic Diabetes.**—The authors found that removal of the pancreas from normal dogs may be followed by the appearance of sugar in the urine within a period of two hours. Glycosuria fails to manifest itself after pancreas extirpation in dogs that have received previous injections of hydrazin. In general this effect is produced by a single subcutaneous injection of 50 mg. per kilo hydrazin sulphate. The influence of the hydrazin administration lasts between two and four days. A single injection of 25 mg. per kilo hydrazin sulphate does not prevent sugar elimination in the urine, under the experimental conditions, after pancreas removal. The blood-sugar content of animals treated with hydrazin and then depancreatized remains below the normal, or at least hyperglycemia is not in evidence. Hydrazin introduced into dogs during pancreatic diabetes is capable of completely inhibiting the excretion of sugar by the kidney. After hydrazin administration the presence of adrenalin in the adrenals may still be demonstrated. In this respect hydrazin differs from phosphorus. The authors assume that there is an interrelation between the pancreas, the adrenals and the liver by the equilibrium of which the sugar content of the blood is kept practically constant. To accomplish this the pancreas is assumed to pour an internal secretion into the blood which tends to increase carbohydrate catabolism, hence to diminish the blood-sugar. This influence they have called the pancreas secretion factor. On the other hand, the adrenal is assumed to give an internal secretion to the blood which has the opposite effect, namely, it has a tendency to check carbohydrate catabolism; hence leads to an accumulation of sugar in the blood. This action they have designated the adrenal secretion factor. According to this idea of what occurs to keep blood-sugar content normal, the quantity of glycogen which will be taken from the liver's store to accomplish this purpose is entirely dependent on which of the two factors is predominant at any given moment. Applying these ideas to pancreas extirpation or adrenal removal, the effects which should theoretically follow according to their scheme agree perfectly with recorded observations which for the most part have universal acceptance.

1. **Transplantation of Segment of Small Intestine.**—In the case cited, Fenwick did a colotomy for cancer of the sigmoid. Three months afterward he resected the growth and did the following transplantation: A loop of ileum fairly low down was taken and a portion about 5 in. in length was double clamped off. The bowel was divided between the clamps and the mesentery, with great caution to avoid blood-vessels towards its root, for a distance of 2½ inches. The continuity of the small gut was next restored by uniting the cut ends in front of the mesentery of the freed segment. The segment of the small intestine, it was found, could easily be brought into excellent position between the cut ends of the large. It was decided to employ two Murphy buttons, no risk of leakage existing because the colotomy was above the proposed junctions. This was accordingly done and proved not very difficult. After the anastomoses were completed a few stitches were placed, drawing together the cut edges of the mesenteries to avoid the possibility of internal hernia. Finally, the abdomen was closed rapidly by interrupted fish-gut sutures, and a rubber tube, with some gauze packing, was inserted at the lower end of the incision. The whole operation, from first incision to the last stitch, occupied ninety minutes. There was little or no shock.

On the seventh day after the operation the Murphy buttons were found free, the upper in the colotomy, the lower in the rectum. Twenty days after the resection, an attempt was made to close the colotomy under local anesthesia (eucaine). This proved very difficult but was eventually effected. A normal motion was passed just over three weeks after the major operation. The bowels now move naturally every morning and the patient states that very little fecal matter comes through the fistula and then only when straining at stool. Throughout the rest of the day he suffers no inconvenience.

6. **Lung Syphilis.**—In a series of 1,000 cases, notified as phthisis, Stanley found two certain of syphilis and one doubtful. In the last seven years he has collected fifteen cases, some of which have come to post-mortem examination and some are still under observation—observation which confirms the opinion that they are syphilitic and not tuberculous. The lesions produced by syphilis are various and may affect the lungs and pleura only, or the trachea and bronchi. There may be lesions in the secondary or tertiary stages. Those due to secondary syphilis are not of much clinical importance, but at the same time should not go unrecognized. The chief interest, however, is in the lesions produced in the tertiary stage. They are various and a clear idea of them is necessary for diagnosis during life and it must be admitted that descriptions of the morbid anatomy of late syphilitic lung lesions are not clear. The trachea, bronchi, lung tissue and pleura may be affected separately or all together. There may be diffuse mediastinitis. It is the incidence of the lesions in these structures that determines the clinical character of the case. The trachea is particularly liable to tertiary ulceration.

As concerns the lung tissue, the early effects produced by syphilis are: (1) An intense cell proliferation which fills the alveoli and infiltrates the septa, peribronchial, subpleural, and perivascular tissues. It is specially marked in the alveolar walls, causing the epithelium to desquamate. The vessels show the typical changes of syphilis. The process may be general or affect portions only of the lung. It gives a peculiar gelatinous appearance and may be called syphilitic pneumonia. The process is fairly rapid, judging by a case Stanley had under observation, in which the lungs were extensively involved in five or six weeks. It is, in fact, an acute interstitial pneumonia. The next variety he calls early diffuse sclerosis. The lung, which is not misshapen, looks, and still more, feels tough. It is pale in places, in others intensely mottled. It shows great increase of connective tissue in all situations, the alveolar walls particularly. Miliary gummata are plentiful. The most striking change, however, is the large quantity of proliferating elastic tissue. Stained with lithia carmine and thymol fuchsin, it may be seen penetrating in all directions, forming a dense network in the septa around the bronchi and the vessels in the pleura. Proliferation of elastic tissue occurs in tubercle, but in tertiary syphilis the process is much more intense. The alveolar changes are also marked. The spaces are often filled with large cells loaded with pigment. The changes in the vessels are those characteristic of syphilis. The third form is a dense sclerosis. The lung may be contracted and misshapen, the pleura, whether adherent or not, is much thickened. Lastly, while there may be gelatinous infiltration, diffuse early sclerosis or intense fibrosis without coarse gumma, Stanley has not seen coarse gumma without some or all of these lesions. Thus one may regard the infiltrative and fibrosing lesions as the most important.

The symptoms and signs vary. There may be none definite when the lung is undergoing partial gelatinous infiltration and even when the lesion is an extensive sclerosis they are difficult to appreciate fully. Weakening of the breath sounds is considered an important sign and was noted in three of Stanley's cases. Symptoms and signs of lung syphilis are much more definite when the lesions are chronic. Hemoptysis is more suggestive of slow ulceration of a bronchial surface in its mucosanguineous appearance and its tendency to last for several weeks. Cough is irregular and may be paroxysmal, as happened in four of Stanley's cases. It may be very slight in proportion to the actual amount of lung lesion, for in another case it was never a prominent symptom, but on the postmortem examination there was extensive lesion of the lung tissue, but none of the bronchi, trachea, or glands. In a case quoted it was particularly interesting to note pyrexia, sweating and wasting, symptoms which occurred in some of the other cases and have been recorded by other observers. They may be regarded as intercurrent and due to mixed infection, but they certainly help in the imitation of phthisis by syphilis. Their rapid disappearance under antisyphilitic treatment is striking.

9. See The Journal, October 14, 1911, p. 1325, abstract No. 64.

12. **Mania Following Pneumonia.**—The cases to which Tyson calls attention are those in which the mania follows the pneumonia and he has had the opportunity of seeing three of these cases; the literature contains only six others. The following are the characteristic points in this form of pneumonic mania: The pneumonia is of the stenic or classical type. The people affected are mostly of a neurotic temperament. It generally happens in youngish people under 40 years of age. It is associated with great sleeplessness and there seems great difficulty in the treatment of this symptom. The disease need not necessarily be very acute or much lung involved. In fact, the amount of lung involved does not seem to bear any relation to the amount or length of stay of the mania. It occurs after the crisis. The delirium that occurs early in the disease is a much more severe type of mania than the mania following the crisis. The pathology, Tyson supposes, is toxic, but he is unable to say why some suffer in this way and others do not. The prognosis of this mania is good and it should be looked on as part of the pneumonia and should not be specially treated as a case of mania *per se*, and the question of asylum treatment need not be considered. Tyson mentions this point because in one of his cases the physician in attendance considered the mania should be treated in an asylum. Perhaps the most important thing in this trouble is to treat the sleeplessness. Food is the best hypnotic, but it may be necessary to give some morphin or some other narcotic. The bowels should be attended to. A tactful, wise and firm nurse is a necessity, and convalescence, if possible, should be carried out in the country.

15. **Skin Pigmentation.**—As a child Lancashire's patient had a patch of dark skin on the throat, which slowly increased in size. When 16 years old this patch was treated by some strong "peeling" process, after which it remained stationary in size and depth of shade. About last Christmas the discoloration began to spread from the region of the old patch down the neck toward the chest and shoulder on the left side. Recently the extension had become much more rapid. Since the onset the patient had been much troubled by attacks of shooting and stabbing pains in the pigmented area; these came on several times during the day and night and were growing daily more severe. The pain usually lasted a few minutes and—this was the interesting feature—appeared to be rapidly followed each time by a fresh deposit of pigment. The pigment involved the whole area between the sternomastoids and the left side of the neck, also the deltoid region of the left shoulder and a considerable part of the left pectoral region down to the nipple level. The pigmented area is sharply demarcated from the right front of the chest wall by a straight-lined border just to the right of the sternum and therefore just beyond the middle line of the body. The pigment itself is seen to be deposited in the form of large freckles of varying shades from dark brown to café-au-lait. On the chin there was on both sides a much fainter and more diffuse pigmentation, so slight as to be scarcely noticeable. The general health was fair. There were no signs of organic disease. Rest, a bromid draught at bedtime and an anodyne application for the shooting pains produced a remarkable improvement. The pains had ceased and there was no fresh pigmentation. On the other hand, there had been remarkable absorption of pigment, which was everywhere considerably paler.

23. Abstracted in The Journal, Oct. 28, 1911, p. 1491.

24. **Surgical Treatment of Epilepsy.**—There are some cases of epilepsy, says Alexander, that prove intractable to general medical and hygienic treatment, and these, unless the disease be somehow arrested, will soon terminate in imbecility and death. In these cases the affected motor area is covered by more or less edema of the pia-arachnoid and this edema probably so affects the cells of the cortex as to predispose to, or cause, the epilepsy and imbecility. Alexander says we can, by the operation of fenestration of the dura mater, drain these edematous areas and prevent reaccumulations. By the operation the progress of the disease has always been retarded in twenty cases under his operation. In several the fits have stopped and in many have been reduced to fractions of the original number.

25. **Viability of Human Cancer in Animals.**—The method adopted by Williams was that of implanting subcutaneously, with aseptic precautions, several selected portions of a malignant growth, freshly excised (pieces being put aside for microscopic observation) and following up the changes taking place in the cells of the growth by reference to sections of the implanted masses, removed for examination at different periods. The time elapsing between separation from the human body and the completion of implantation varied between twenty and twenty-five minutes. Implantation was effected by puncturing the skin with a straight cataract knife

and introducing on the point of the knife a piece of tissue aving the form of a cube of 1 to 1.5 mm. The portions of umor implanted were removed at intervals of one to thirteen ays. The number of tumors used for implantation was rty-one: ten tumors were, however, employed in connection th unsuccessful implantations, so that only thirty-one need referred to here. Of these, nineteen were epithelioma venteen primary growths, two secondarily infected glands), were scirrhus of the breast (nine primary growths, one ndarily infected gland), one was spheroidal-celled carci- a and one rodent ulcer. plantation was made on the monkey (twenty tumors), oit (four tumors), pigeon and guinea-pig (each two tumors), cat, rat and mouse (each one tumor). The usual causes of unsuccessful experiments were suppuration and failure to recover the pieces of tumor implanted. Suppuration was not met with so frequently as was expected, even in the case of growths ulcerated on the surface; when present sometimes every piece of a tumor used for implantation became the seat of suppuration, in other cases suppuration occurred at some of the sites of implantation, while at others no inflammatory reaction occurred. A more serious difficulty was failure to recover the portion of tumor implanted. Portions of human carcinoma implanted into animals were observed during the first five days to retain their vitality and to exhibit mitosis after implantation. After the expiration of this period no evidence of vitality was observed. Mitosis was markedly inhibited within twenty-four hours of implantation, while the life of the implanted cells was abolished less rapidly.

26. **Salvarsan, Mercury and Iodid of Potassium as Antisyphilitics.**—The authors found that salvarsan in experimental syphilis of the rabbit possesses spirocheticidal properties much in advance of mercury. Potassium iodid is not a direct antisyphilitic.

28. **Foreign Bodies in Vermiform Appendix.**—Bidwell has found a foreign body in about 20 per cent. of the appendices which he has removed. The interesting point is that a foreign body by itself sets up very little irritation and does not produce acute inflammation; it is only when a fecal concretion forms around it that acute appendicitis will occur. According to many authorities, no foreign body or fecal matter can enter a healthy appendix, and it is stated that some previous inflammation must occur in order to make it possible for the body to enter. If this is the case, a foreign body by itself could not have very much influence in producing appendicular disease. It is, however, more reasonable to suppose that the irritation of the foreign body excites an extra secretion of mucus, which is deposited on the body, producing the concretion and so becomes the starting point of an attack of appendicitis.

35. **Consumption and Order of Birth.**—Rivers observed in patients' case-sheets which showed ordinal position in the family, a large number of entries of eldest-born children, and from this observation conceived the idea that clinical pulmonary tuberculosis might affect such persons more than others. Brehmer's and Riffel's reports show that both first- and second-born offspring appear subject to consumption at a very much higher rate than younger members of a family. Rivers' own observations in 263 cases confirm those of other clinicians. Mitchell, among 443 idiots and imbeciles, found 138 first-born, or 31.1 per cent. Langdon Down claims liability to idiocy among primiparous children because 24 per cent. of the 2,000 idiots (illegitimate largely excluded) examined by him were first-born children. Among Wilbar's 675 there were 191 first-born; among 100 of Beach's, twenty. Thus, respecting the exact amount of increased risk of developing phthisis that an eldest child runs, no direct data exist from which to calculate. As matters stand, one may say that whereas in 1,228 consumptives (494 upper middle-class Germans; 353 middle- and lower-class inhabitants of Lancashire, London, and Northumberland, and 381 mainly lower-class Lancastrians) one should find 196 eldest children, one actually does find 281, i. e., eldest-born consumptives are in excess, say, 40 per cent.

Of 141 of Rivers' last cases there is one patient with diabetes mellitus, three who suffer from hay fever, and three the subjects of congenital xerodermia. The diabetes patient is an eldest child; two of the hay fever patients are likewise, while the remaining one is second-born, and two of the ichthyotics are eldest-born. Yet the first- and second-born of these 141, only number fifty-eight and the first-born alone only twenty-eight. This, in Rivers' opinion, would seem to point to the conclusion that the tendency of the eldest-born to become consumptive is an innate tendency and the hypothesis is strengthened, he says, if we appeal to the literature of the subject. Lunatics and idiots are certainly very liable to consumption, and, as has been seen, it is exceedingly likely that they are disproportionately often eldest-born. Again, if faulty upbringing by inexperienced parents is to be made responsible for elder-born criminals, lunatics, idiots and perhaps men of genius, this would render ordinary human responsibility sufficiently formidable. The existing evidence negatives the view that infection is the sole cause.

37. **Strangulation by Volvulus.**—In the mid-region of the abdominal cavity in Knaggs' case was a large rounded cyst or sac, through the semi-transparent wall of which distended coils of bowel could be seen. The upper coils were large and pale and had a somewhat transverse direction; the lower were black, as if the subject of strangulation, and had an obliquely-vertical arrangement. Below the cyst, the lower portion of the abdomen, which was little more than the pelvis, was occupied by coils of black small intestine which concealed the terminal portion of the large gut. Above the cyst and encroaching on its shelving upper surface, lay the liver, and in the left hypochondrium the stomach. The great omentum was huddled up into a mass which fitted into the space between the cyst and the stomach. The colon was not visible, but it was found to encircle the cyst, except at its lowest part, and to be attached to its wall. To permit of the further investigation of parts the strangulated small bowel occupying the area below the cyst was removed. It was a single loop some 3 or 4 feet long and the two ends of the loop passed into the cyst through an aperture on its lower surface. The two ends were tied a few inches from the aperture. The whole loop was deeply congested, of a purplish-black color and infiltrated with blood. It was not constricted at the neck and the finger could be introduced alongside the gut through the aperture into the cyst. The entrance to the sac looked downward and was on the level of the promontory of the sacrum. It was large enough to admit three fingers. The cyst occupied the small intestine area within the arch of the colon.

To continue the examination it was opened by a central vertical incision through its whole length which terminated by dividing the boundary of the aperture. The two cut ends of the strangled loop were continuous with similarly affected coils within the sac. There had been no strangulation by the neck of the sac and no signs of constriction were presented by the portions of bowel that occupied it. The greater part of the ileum was in this deeply congested state, which was evidently due to a twist of the lower portion of the mesentery, but the exact mechanism was not made out, as owing to the inexperience of the manipulator the relations were disturbed and lost, and the previous removal of the loop outside the sac added to the difficulties of its demonstration. The jejunum was distended but not strangled. On the posterior surface of the sac was the quite normal attachment of the mesentery. It lay entirely within the sac. At the upper part the third and fourth parts of the duodenum were in their natural position and covered as usual by peritoneum. The terminal portion of the ileum passed out of the opening to join the cecum, which lay just outside and to the right of the mouth of the sac. The ileum at this point was attached by its mesentery, which blended with the margin of the aperture on the right side. The condition may be fairly described as a second and abnormal lesser peritoneal sac, whose natural contents were the small intestine and its mesentery. Some of the contents had escaped through the orifice into the general peritoneal cavity.

40. **Persistent Chyluria.**—When Charteris' patient was right the urine was practically free from fat, but if he lined at an angle greater than 45 degrees, he promptly gan to pass milky urine; but if he sat in an upright chair the urine remained clear. The most milky urine was passed when he lay flat on his back. On the other hand, he could lie flat on his face without the urine becoming milky, but it became milky as soon as he turned round and lay on his back. The conclusion Charteris came to was that the chyluria was due to some intermittent pressure exerted on the thoracic duct by some factor which only became operative when the patient assumed certain attitudes. Probably the obstruction was a pedunculated calcareous gland. There was no enlargement to be felt in any of the abdominal glands and a Roentgen-ray examination failed to reveal any calcareous masses.

58. **Nervous Complications of Gastric Ulcer.**—Klippel and Weil think that they were the first to call attention (1909) to polyneuritis developing as a complication of gastric ulcer. Their assertions were confirmed by Couréménos and Conos. Other disturbances in the digestive tract have been incriminated as the cause of nervous disturbances, Christani having reported a case of polyneuritis from coprostasis. and Duvernay one of peripheral neuritis from stasis of stomach content, and cured by a gastro-enterostomy. Babinski ascribes peripheral neuritis in some cases to auto-intoxication from the intestine and Klippel has reported cases of neuritis from changes in the liver. In the two cases reported in detail the diagnosis of gastric ulcer was unquestionable, as also in a case cited from the literature; all had paresis with loss of the deep and superficial reflexes while the nerves and muscles were more or less tender—the syndrome indicating flaccid quadriplegia resulting from polyneuritis. There was nothing to suggest tabes, but in one case the neuritis was more of the Korsakoff type. In another case reported the clinical picture suggested tabetic gastric crises in an old syphilitic, but the trouble proved to be a polyneuritic pseudotabes complicating gastric ulcer in a syphilitic. As the gastric ulcer had caused no appreciable symptoms, the pain had been the first sign of trouble. It is probable that many of the cases published as hemorrhagic tabetic gastric crises belong in this category of gastric ulcer complicated by polyneuritis. There have been thirteen of these hémorrhagic gastric crises cases reported in French literature.

61. **Surgery of the Spleen.**—Hartmann describes with fifteen illustrations the surgical treatment of spleen affections and discusses the results to date in various clinics. The high mortality with rupture of the spleen imposes an immediate operation, he says, and splenectomy offers the best prospect for success. With the enlarged spleen of malaria, splenectomy seldom does much good unless the spleen is compressing the neighboring organs. Fevrier found a mortality of 26 per cent. in 117 cases of this kind, but it was only 13 per cent. in Johnston's sixty-one cases since 1900, and if the splenectomy is restricted to a movable malarial spleen, the mortality is still less, there having been only one death in Bessel Hagen's twenty-six cases.

63. **Epilepsy Consecutive to Typhoid.**—Chalier and Juilhe report the case of a previously healthy young man who developed epilepsy after a severe attack of typhoid, the seizures typical of true epilepsy during the six years to date. Dide found typhoid antecedents in seven of 120 epileptics examined. The typhoid evidently induces injury of the nerves and the resulting cicatrix becomes one of the causal factors of the epilepsy. Such a cicatrix may remain latent until some disturbance in the circulation or other insignificant cause may bring on what Pierret calls recall phenomena. These phenomena may be motor, sensory or psychic, or they may be of the type of the epileptic seizure.

66. **Placenta Prævia.**—Schweitzer reviews the experiences in the last four years with 100 cases of placenta prævia at the Leipsic maternity in charge of Zweifel. These later experiences teach, he says, the advantages of hastening delivery when there is severe hemorrhage in the second half of pregnancy. Rupture of the fetal membranes is the prefer-

able procedure, but when this does not succeed in arresting the hemorrhage or the presentation is not favorable he uses the inflatable bag if the mother and child are in good condition; he prefers combined version if the mother is growing weak and the child is dead or not viable. Cesarean section should be preferred for the cases of threatening hemorrhage, the cervix still closed; in the infected cases, combined version with perforation or perforation alone at once. He advises in the home, combined version and patient waiting for spontaneous expulsion. Every effort should be made to insure asepsis and prevent further loss of blood. His observation having shown that the blood has less coagulating power when there has been considerable hemorrhage, he uses an astringent tampon, the gauze dipped in alcohol or a solution of alum instead of the ordinary iodoform gauze. Hysterectomy may be required for threatening after-hemorrhage from laceration or atony.

69. **Retroflexion of the Uterus.**—Lehmann has examined 100 women, including fifty with retroflexion and fifty without, after filling the bladder as full as possible and having the women recline or stand alternately and then examining them again half an hour after the bladder has been emptied. He devotes twenty-four pages to the tabulated findings in each case to study whether the bladder functioning can alter the position of the uterus, his conclusions being negative. Other experiments showed that the uterus can correct its position by contraction of the musculature under the influence of induced electricity, but the long application and the strength of the current required render the procedure scarcely applicable in the clinic to date. Of the total 2,000 patients with dislocations of various kinds, thirty-seven were permanently cured by pessary treatment alone; there were no complications in seven cases, but thirty patients with some slight affection in the ovaries or tubes or around the uterus had the displacement cured by the pessary treatment alone. His experience thus indicates that mild complications rather favor pessary treatment.

76. **Tuberculosis in 3,514 Female Cadavers.**—Schlimpert found signs of tuberculosis in 2,173, that is 61.8 per cent. of the total 3,514 cadavers, but in only 29 per cent. had it been diagnosed during life. His figures show further that nearly 50 per cent. of the population furnishing the material die of tuberculosis. The highest mortality from tuberculosis was between 20 and 30, next in the three following decades. The lungs were affected in 84.3 of the 2,173 tuberculous cadavers, the intestines in 32.3, the peritoneum in 4.9 and the genitals and meninges in 3.35 per cent. each, the pericardium in 2.2 and the urinary system in 1.4 per cent. No evidence of a primary isolated tuberculosis of the genital organs or of the urinary apparatus was discovered in any instance. A blood-borne origin was possible in the majority of the genital cases, probable in twenty-eight of the seventy-three cases and certain in five. The peritoneum was involved in 42.5 per cent. of the seventy-three cases of genital tuberculosis. There was no case in which the genital tuberculosis seemed to have been the cause of death; in 95.9 per cent. death was due to tuberculous lesions elsewhere. In the tuberculosis of the urinary system, infection was blood-borne and descending in most cases. Nearly 8 per cent. of the 3,514 women were pregnant or had just been delivered, and 139 of these 273 were tuberculous, that is, 15.9 per cent. The data confirm the assumption that tuberculosis is aggravated by child-bearing.

82. **Mesothorium.**—This is a radio-active substance which is being extensively investigated in Germany, as there is no production of radium in that country, while mesothorium is an accessible by-product. The present article reports research on the action of the rays on the digestive ferments, part of the research now under way on the biologic action of mesothorium.

85. **The Two-Route Method in Treatment of Lupus.**—Schaumann describes excellent results in a case of lupus of the face and hard palate in which he applied Pfannenstill's method, acting on the lesion by potassium iodid taken internally and application of ozone or a dioxid externally. The latter was applied by means of a prothesis fitting over the hard palate, holding the impregnated cotton against the lesion. He ascribes the benefit to a caustic action of the combining drugs, as the efficacy depends on the setting up of an ulceration. He therefore warns that the method is not applicable to lesions on the face as it is liable to induce mutilation which is unnecessary by the Finsen method of radiotherapy.

Correspondenz-Blatt für Schweizer Aerzte, Basel

October 1, XLI, No. 28, pp. 961-992

87 *Treatment of Heart Disease. (Behandlung von Herzkrankheiten.) H. Eichhorst.

87. **Heart Disease.**—Eichhorst reviews the general principles of treatment of heart disease, insisting that the general practitioner often fails to appreciate the wonderful benefit that can be derived from rest and nourishing food, without drugs. He is liable to ascribe the benefit to the drug he happens to prescribe, but it cannot be emphasized often enough, Eichhorst insists, that complete repose is the most indispensable measure in treatment of weakness of the heart muscle whether drugs are given or not. Next in importance is the diet, especially milk. Milk is easily digested, nourishing and has a diuretic action, but even this should not be allowed in excess and not for too long. The Karell cure often renders good service in heart disease with edema. The patient is given only 200 c.c. of milk four times a day for four days, and the edema disappears and the heart action improves remarkably even in cases refractory to drugs. He warns, however, that the Karell cure may induce collapse in rare cases, so that it is scarcely advisable outside of an institution. If repose and a milk diet have proved inadequate by the end of twenty-four or forty-eight hours to strengthen the myocardium, it is time to give a heart tonic unless conditions had imposed the necessity for this from the start. Another measure which he has often found useful is upward stroking of the edematous legs, the feet raised for a time morning and evening, with passive flexion of the legs at the ankles, knees and hip joints, striving to pump the edema out of the legs. Mechanical measures, puncture or incision, have been known to entail fatal collapse, as also hot air baths, but venesection often gives surprising relief. When the heart has recuperated, the physician must insist on physical and mental rest; physicians seldom recognize the importance of emotional factors in heart disease. Eichhorst reports three cases in which young people with well compensated heart trouble died suddenly after a sudden emotion of anger or delight. Strict individualization is necessary in deciding as to marriage for girls with valvular defects: he has a patient of 39 who has borne seven children without mishap, notwithstanding mitral stenosis since the age of 10, but delicate, anemic, sensitive girls should be dissuaded as a rule from matrimony.

89. **Spectroscopic Diagnosis of Occult Blood.**—Csepai asserts that examination of the stools for traces of invisible blood with the spectroscope gives far more reliable findings than chemical or other tests for occult hemorrhage. The reagents needed for the work are cheap and durable while the technic is simple and rapid. He has the patient refrain from meat and green vegetables for three days before the examination. Then to 5 gm. of the stool are added 5 c.c. of concentrated acetic acid plus 5 c.c. ether and 5 c.c. alcohol. The mixture is ground up well in a mortar and then filtered through an unmoistened pleated filter until 2 or 3 c.c. of fluid collects in the test tube. He then adds 1 or 2 c.c. of pyridin to the extract, then 1 or 3 drops (no more) of ammonium sulphid solution; the spectroscope then shows the spectrum for hemochromogen if there are traces of blood in the fluid. The test is complete in six or eight minutes. The reagent $(NH_4)_2S$ must be made up fresh and be kept in a dark colored bottle with glass stopper. It keeps perfectly for ten days. No time is to be lost after adding the reagent before examining with the spectroscope as the spectrum soon fades. An ordinary spectroscope with artificial light answers the purpose. He tabulates the comparative findings with this and other tests, all showing the reliability of this simple technic and that it is as sensitive as the catalytic tests.

91. **Ridges in Rectal Mucosa.**—Lindenberg found one to six folds or valve-like protrusions in the rectal mucosa in all but one of nine cadavers examined with the rectoscope.

92. **Mercuric Chlorid Hemolytic Test.**—Port examined the serum of thirty-one patients with various affections to determine the relative protecting power of the individual serum against the hemolytic action of mercuric chlorid and of saponin. The index of the protecting power was abnormally low with gastric cancer, pregnancy nephritis and tuberculosis, while it was abnormally high in diabetes, typhoid and severe parenchymatous nephritis.

97. **What Becomes Later of "Growth Hypertrophy of the Heart" and Juvenile Arteriosclerosis.**—Faber has been reexamining lately thirty persons who in youth presented signs of what was called at the time "growth hypertrophy of the heart" or juvenile arteriosclerosis. He tabulates the clinical findings then and now; in very few has the cardiovascular system developed to entirely *normal conditions* since. There is still in the majority some evidence that this system is a little below par.

102. **Mosquito Poison.**—Bruck has isolated from the common mosquito its toxin, which he calls culicin. He obtained it by grinding the mosquitoes, *Culex pipiens*, in a mortar with salt solution containing a little glycerin and centrifugating. He found that culicin contained a hemolysin and an urticaria-producing principle, and describes research with it and research on mosquitoes to find whether they could convey the syphilis spirochetes. He never was able to get the mosquitoes to bite a syphilitic lesion; they always avoided the morbid tissues and settled only on the sound tissue encircling them. At the same time he found that the mosquitoes can take up spirochetes on their feet and thus transmit infection. In his one positive experiment in this line, from a mosquito that had been in contact with a primary sore on a rabbit and, fifteen minutes later, had had its legs rinsed with salt solution, he obtained a motile, unmistakable *Spirochæta pallida*, which was found in the rinsing water.

107. **Cancer of the Bladder.**—Riese removed a carcinoma from the bladder of a woman of 66 over a year ago and there has been no sign of recurrence since. In another case the patient died of senile weakness four years after removal of a carcinoma occluding the mouth of the left ureter in the bladder. There was no sign of recurrence in this case and neither in a third case in which the interval since has not been so long. He removed the bladder on account of sarcoma in a girl of 10 with gonorrhea, but the debilitated child succumbed an hour later. Notwithstanding the fatal outcome in this case, he is convinced that removal of the bladder for malignant disease is not a difficult operation, comparatively speaking, and it offers good prospects in appropriate cases.

109. **Pulsating Exophthalmos.**—The exophthalmos may be the result of an arteriovenous aneurysm of the internal carotid in the sinus cavernosus. When this is the case the symptoms are characteristic, especially the cessation of the pulsation and noises when the carotid is compressed. Systematic compression of the common carotid is suggested by Zeller as a logical method for relieving and curing the trouble, permitting a collateral circulation to develop, while the heart is trained to its increased task and it is determined whether the patient is able to stand the exclusion of the carotid. If symptoms on the part of the brain develop under compression of the carotid, ligation of the carotid is contra-indicated. If the systematic compression fails to relieve, Zeller severs the internal carotid between two ligatures as close to the base of the skull as possible. The external carotid should not be

ligated, for reasons which he enumerates. A course of tonics and heart stimulants should precede the operation if necessary, and it should be restricted to the severest cases. It can be done under local anesthesia. If no brain symptoms develop under systematic compression of the carotid, the ligation is not contra-indicated even in the elderly. Heart tonics and venesection may be needed after the operation. He discusses the experiences in this line on record to date, with the various attempts that have been made to cure pulsating exophthalmos, and reports a case of traumatic origin. His cases teach the value of ligation of the internal carotid in these cases and that ligation of the external branch is useless. Complications in his case prevented a successful outcome, but the phenomena observed in this case possibly point the way to successful management of such cases in future.

115. **Nerve Blocking in the Thigh.**—Läwen has been studying the best technic for injecting an anesthetic into the thigh to block conduction of pain in the sciatic nerve, similar to Braun's *Leitungsanästhesie* of the leg. The anesthetic seems to diffuse into the nerve trunk or the special ganglia or even into the spinal cord, and thus arrest the pain. The anesthesia thus induced permits in thin patients a painless amputation. The patient lies in the ventral decubitus and the needle is inserted at a point 2 cm. outside of the tuberosity of the ischium, and about 20 or 30 c.c. of fluid is injected perpendicularly at the assumed depth of the nerve trunk. Then the needle is partly withdrawn and pointed outward and a little more of the anesthetic is injected. The perpendicular injection blocks the tibial nerve, especially if a little stronger concentration of the anesthetic is used at this point. Then the needle is introduced again at a point 3 cm. inside of the greater trochanter, slanting it inward a little and ejecting the liquid at three depths, pointing it so that all the soft parts between the two injecting points are infiltrated with the solution. In one of the ten cases reported in detail he thus blocked the nerves, including the femoral, tibial and obturator, using a total of 1.8 gm. novocain in thirty minutes, with the result that the whole leg became insensible to needle pricks and the leg was amputated without the slightest pain, not even when the nerves were pulled. He thinks this technic for the injections is promising for treatment of sciatica.

119. **Cholelithiasis.**—Schultze outlines a certain method of procedure for differentiating gall-stone disease by exclusion. He first seeks to exclude epigastric hernia, the symptoms from which may simulate those from gall-stones; then he excludes circumscribed peritonitis, gastric ulcer and cancer. With the former the pains are connected with the meals, while in cholelithiasis the attacks of pain may occur at any time, often suddenly in the night. Duodenal ulcer, and affections of the small and then of the large intestine are next considered. Especially with nervous and membranous colitis, the pains are liable to resemble those with gall-stones except that they recur more frequently, and are not accompanied by jaundice. Appendicitis may induce adhesions causing disturbances similar to those from gall-stones. With acute pancreatitis the collapse is severer than with gall-stone colic and the stomach region generally protrudes while otherwise the trouble may suggest ileus. The possibility of gastric crises should also be borne in mind and the reflexes tested and hyperesthetic zones sought for. Schultze has had cases of coincident gastric crises and gall-stones. Calculi in the kidney may be excluded by roentoscopy and wandering kidney by manual examination. With pain from spastic conditions in the stomach or intestine, the gall-bladder is not specially tender. Differentiation of cholelithiasis is unusually difficult when the patient is inclined to hysteria. Tenderness on palpation of the right hypochondrium and especially at the point where the ninth intercostal nerve pierces the rectus muscle, is the most reliable sign of gall-stone trouble when connected with colics. Another characteristic sign is the radiation of the pain to the right shoulder and into the right arm. In some cases this radiated pain dominates the clinical picture, and the patients are treated for years for assumed neuritis until passage of a gall-stone cures the "neuritis." When "neuralgia" of this character is complained of, the skin of the upper abdomen should be tested for extrasensitiveness to contact. The right upper abdominal wall is also liable to be left rigid during and after gall-stone colic. Schultze insists on bed rest, possibly for weeks, for patients with gall-stone pains until the region is no longer tender. Hot compresses to the upper abdomen and hot water internally aid in the cure, supplemented by plenty of water to drink and five meals a day of readily digestible food to keep the bile flowing freely. The meal is the best cholagog, he adds, and no pharmaceutical means are known to dissolve or expel gall-stones.

122. **Immobilization of the Arm in Treatment of Pleurisy.**—Kuhn ties the wrist of the affected side to the thigh on the other side, thus preventing any movement of the arm and shoulder and giving the inflamed pleura a chance to heal. He has found this measure very useful in several cases of pleurisy without effusion, fastening the arm down under the clothing and not releasing it until the temperature was permanently normal. He warns that tuberculosis contra-indicates this measure as the immobilization is not complete enough to be beneficial in this infection; the partial immobilization thus induced tends rather to aggravate a chronic process.

123. **Breathing Exercises in Treatment of Nasal Catarrh.**—Dannehl applies cool air to reduce the congestion in the nose, having the patients breathe moderately deep through the most congested side, expelling the warmed air rapidly through the mouth, inspiration longer than expiration. The best method is to do these exercises during a tranquil walk morning and evening. If they have to be done in the house, he has the patient recline on each side in turn during the breathing exercises. He reports excellent results from them even in chronic catarrh.

132. **Diagnostic Importance of the Babinski Sign with Impending Uremia.**—Curschmann called attention some years ago to the great importance, both for diagnosis and prognosis, of modifications in the reflexes as a sign of the morbid condition preceding the uremia syndrome. The various reflexes may be exaggerated or abolished, but he has invariably found the Babinski sign permanently positive from the start, even in cases with loss of all the other tendon reflexes. Little attention has been paid to his statements in regard to the importance of this sign of impending uremia and he here reaffirms them anew and relates a number of typical examples. The first patient was a boy of 10 with acute nephritis but unimpaired consciousness, the tendon reflexes abnormally weak, the abdominal wall reflex abolished, but the Babinski sign phenomenon was pronounced on both sides, and Curschmann, solely from this fact, assumed impending uremia and began prophylactic treatment, venesection, saline infusion and heart tonics. Sixteen or eighteen hours later the uremia made its presence known by convulsions, but the next day improvement was evident and the boy recovered, the Babinski sign subsiding as the convulsions ceased. The contrast between the behavior of this sign and of the other reflexes is particularly characteristic of impending uremia; in some cases the other reflexes may be exaggerated during the uremic phenomena but the Babinski sign warns of danger hours before. He has witnessed in some cases exaggeration of the tendon reflexes during suburemic phases of chronic nephritis. This characteristic behavior of the Babinski is liable to occur with all forms of nephritis, except that he found the forms tending to edema more inclined to exaggeration of the reflexes than the nephritis without this tendency. In conclusion Curschmann discusses the mechanism of and theory for this behavior of the Babinski sign as the purest expression of the loss of cerebral inhibition.

151. **Placenta Prævia.**—When the placenta is inserted in the cervix the lip of the os protrudes, the cervix ballooning, resembling the aspect of an abortion impacted in the cervix, the suggestion of abortion being reenforced by the signs of pregnancy and preceding hemorrhages. Sometimes the cervix is friable. If the external os is open a little, crumbling masses can be palpated above it, which bleed at a touch, in the early stages the condition resembling malignant disease. Hofstätter reports a case in which the diagnosis was correctly made; the patient recovered notwithstanding profuse hemorrhage from the inability of the lower segment of the uterus to contract properly. In future in such a case he would at once remove the uterus by the vagina unless there had been only a slight loss of blood, in which case he would try to master the situation by delivering the child, separating the placenta and applying a firm tampon, ready to do hysterectomy at once in case the hemorrhage persisted. He warns that it is impossible to count on spontaneous separation of the placenta from the site in the cervix.

152. **Tuberculin Treatment of Urogenital Tuberculosis.**—In this communication from Zuckerkandl's surgical service the experiences with twelve patients with tuberculosis of the kidneys given tuberculin treatment are reviewed, the conclusions being that operative cases do not require tuberculin treatment unless the tuberculosis involves other organs besides the kidney; in this case tuberculin treatment is advisable. In the rare cases in which the tuberculosis is detected in its early stages by discovery of tubercle bacilli in the urine without essential suppuration or impairment of kidney functioning, tuberculin treatment may give fine results. The experiences related do not show that the focus is liable to heal under tuberculin treatment, but the general health improves and the patients gain in weight. The tuberculin treatment should never be carried to a point to induce reaction. In the inoperable cases it may be applied as a last resort.

168.*Influence of Injections of Gelatin on Kidney Disease. (Zur Frage des Einflusses der subkutanen Gelatineinjektionen bei Nierenerkrankungen.) J. B. Studzinski.

168. **Injections of Gelatin in Kidney Disease.**—Studzinski reports his experiences and analysis of the findings in fourteen cases of kidney disease and in two healthy persons with sound kidneys, all given subcutaneous injections of gelatin in the hope of influencing a hemorrhagic tendency. He did not find any modification of the amount or specific gravity of the urine in any case with the ordinary technic. With chronic interstitial or parenchymatous nephritis without parenchymatous hemorrhages, the injections did not seem to do any special harm as only in one case did they transiently increase the amount of albumin and formed elements in the urine. When the kidney disease was accompanied by a tendency to parenchymatous hemorrhage in the kidney, the injections not only failed to arrest the hemorrhages but dis-

tinctly aggravated this local hemorrhagic tendency. Internal administration of the gelatin, on the other hand, is free from danger and may be of some use without causing any untoward by-effects. The case of uremia reported by Bauermeister in which fatal symptoms of uremia followed the internal administration of gelatin, is probably explainable by the preexistence of the uremia. This patient was given the gelatin for uterine hemorrhage and epistaxis, but the treatment had been preceded by evidence of chronic parenchymatous nephritis inducing uremic disturbances.

187 Antitoxic Power of Lymphatic Glands. (Sul potere antitossico delle glandole linfatiche.) F. Lofaro.

181. The Wassermann Reaction in Foundlings.—Flamini obtained a positive reaction in thirteen of 170 foundlings at the Rome asylum. This proportion of 7.5 per cent. is about the same as that obtained at the Milan asylum. It is much lower than the proportion of positive reactions in the blood from the umbilical cord obtained in maternities. He thinks that this testifies to the presence in the blood of substances from the maternal blood which give the Wassermann reaction.

186. The Cobra Reaction in Surgical Affections.—Aperlo has been applying Calmette's cobra venom test in fifteen cases of surgical tuberculosis, three of sarcoma, four of carcinoma and eight with various other surgical affections. The reaction was positive in all the sarcoma cases and negative in the carcinoma. In the tuberculous cases the cobra reaction alone was positive in three, the cutaneous reaction alone in four, and both were positive in five other cases. He reports these findings without drawing any general conclusions from them.

192 *The Wassermann Reaction and Its Clinical Importance. (Den Wassermannske reaktion og dens kliniske betydning.) R. Krefting.

190. Obstacles to Marriage from the Medical Standpoint.—Holmboe was commissioned by the Norwegian government to report on this subject, and he here presents the results of his study. The questions involved were principally determination of the lowest age-limit for candidates for matrimony, mental or physical disease or consanguinity as an obstacle to marriage, and whether persons known to the authorities to be suffering from contagious or heritable diseases should be allowed to marry, and whether medical examination of candidates for matrimony should be made compulsory. He states that according to the statistics at hand, the girls of the wage-earning classes in Norway as a rule begin to menstruate late, one-fourth not until after the seventeenth year, consequently he thinks that the lower limit for matrimony should not be under 18. It is 16 according to the present legislation. His conclusions are unfavorable to compulsory medical examination of candidates as liable to prove illusory for reasons which he enumerates.

192. The Wassermann Reaction.—Krefting's monograph is published as a separate pamphlet of 152 pages and discusses the Wassermann reaction from different points of view, including the historical and life insurance standpoints. He has been studying the reaction for nearly three years and has made 2,500 Wassermann tests. In 322 cases of latent syphilis the reaction was negative in 75 per cent. and he is convinced that these negative patients are more liable to be spared further manifestations of their syphilis than those giving a positive reaction. He has examined a number of these negative patients repeatedly during the last two and a half years and has never obtained a positive response, and this persisting negative reaction is a favorable sign. A positive reaction must be accepted, he thinks, as a sign of active syphilis, no matter what the stage of the disease in question. One of his patients with syphilis of ten years' standing and who had had the disease apparently in a very mild form, gave a positive reaction when tested a year ago after a long period of freedom from manifestations, and yet a month after the test had given positive findings a gumma developed on the thigh. In another case a man of 45 with infection of eighteen years' standing applied for relief from incipient cataract and the Wassermann test was positive. A month or so later a gumma was discovered on the shoulder. Another patient of the same age, with a history of infection seventeen years before but so slight that some physicians doubted the correctness of the diagnosis, gave a positive reaction when tested two years ago and a year later had to be taken to an asylum with acute paralysis, fatal in three months. Some of the patients giving a positive reaction, but apparently free from manifestations of the disease complain a little of their hearts so that there is probably some aortitis or aneurysm developing although no physical signs of such can be detected. In regard to life insurance, Krefting states that he has applied the test a few times on behalf of insurance companies but is not aware that they acted on the outcome of the test; he thinks, however, that the companies will in time have to take the Wassermann reaction into account in dubious cases, and as it is in the interest of the companies, they will have to assume the expense. An interesting chapter relates Krefting's experience with the Wassermann findings under mercurial and salvarsan treatment. It seems to indicate that salvarsan has a more regular and a more pronounced action on the syphilis than any other treatment. He even reports a case of apparent *reinfection* after the patient had been presumably cured under salvarsan of his primary syphilis. He applied for treatment January 19, with a primary sore swarming with spirochetes, the Wassermann negative. Three intravenous injections of salvarsan were given between January 21 and March 10, the Wassermann reaction constantly negative, and no manifestations of the syphilis were observed beyond the primary sore. June 3 the young man returned with two primary sores both swarming with spirochetes and the Wassermann reaction was positive; infection had occurred six weeks before. The syphilis this time ran a somewhat livelier course with roseola and some glandular involvement. Krefting remarks that this is the most carefully investigated case of presumable reinfection known to him, the primary sores each time having been diagnosed as such by other physicians. Krefting never obtained a positive reaction in primary syphilis until seven or eight weeks after infection. He obtained a positive reaction in every one of the 317 patients with syphilis in the secondary stage, including eighty-two women, and in eighty-four of eighty-seven syphilitics in the tertiary stage, the interval since infection ranging from two to thirty years. Among his 322 cases of syphilis free from symptoms, three to forty years after infection, the reaction was positive in 27 per cent.: among the 233 negative cases the patients at some time had had tertiary manifestations.

VARIATIONS IN THE PHAGOCYTIC AND OTHER POWERS OF LEUKOCYTES *

LUDVIG HEKTOEN, M.D.
CHICAGO

In the course of the recent study of phagocytosis, inaugurated by the discovery of opsonic substances in the blood and other fluids, it has been observed by various investigators that, contrary to the original belief of Wright and others, the phagocytic power or activity of the leukocytes is subject to considerable variation independently of variations in the opsonic content of the blood. It is the purpose of this article to review briefly the observations touching variations in the phagocytic and allied powers of leukocytes under different conditions, because it seems to me that the results at hand have a direct bearing on the larger problem of the anti-infectious powers of the blood as a whole.

The phagocytic power of leukocytes from a particular source may be compared with that of other leukocytes by finding the amount of phagocytosis performed by each under strictly comparable conditions. For such purpose the phagocytic mixtures, which would be the same in all respects save for the sources of the leukocytes, self-evidently must contain the same number of leukocytes. Hence standardized suspensions of leukocytes, that is, neutrophil leukocytes, the chief bacterial phagocytes, must be prepared. The number of polymorphonuclear cells in the same volume of each leukocytic suspension, made in the usual way, is determined by counting, and then the stronger suspensions are diluted with salt solution so that all acquire the same density. In other respects the procedure is quite the same as that used for determination of the opsonic content of serum. Of course, the samples of blood and of other fluids containing the leukocytes that are to be studied must be collected at the same time, and all the subsequent manipulations must be carried out under the same conditions in all respects.

This in brief is the general plan of the investigations of the subject in hand, made in this institute by Rosenow, Tunnicliff, Boughton and Eggers. In the case of at least some of the investigations made elsewhere, it is not always clear from the reports in the literature that due attention was given to this matter of having an equal number of phagocytes in the mixtures made for the comparison of the phagocytic power of leukocytes from different sources. This criticism probably applies to one of the earliest observations bearing on this question, namely, that by Ledingham and Bulloch[1] to the effect that the leukocytes of the leukocytosis produced in rabbits, by injection of sodium cinnamate, are less active phagocytically for staphylococci than the leukocytes of normal rabbits. It is quite evident—and Fleming[2] has shown it to be the case—that in mixtures containing an unequal number of leukocytes there will be less phagocytosis per phagocyte in the mixture containing the larger number of leukocytes, and vice versa. In other words, an apparent difference in phagocytic power may result from inequality in the number of leukocytes in the mixtures studied. Using numerically standardized leukocytic mixtures, Rosenow,[3] who also was one of the very first to make extensive studies of the question under discussion, obtained results indicating that in pneumonia the leukocytes have a greater inherent phagocytic power than in health, owing, he suggests, to the preponderance in the pneumonic leukocytosis of younger forms. Not only did he find that pneumonic leukocytes would take up more easily phagocytable pneumococci than normal leukocytes under the same conditions, that is, under the influence of the same serum, but also that the pneumonic leukocytes would take up pneumococci that would resist phagocytosis by the leukocytes of normal blood. Rosenow also observed that pneumonic leukocytes are more resistant to heat, and that after having been heated to the thermal death-point and then resuspended in serum, these leukocytes exercise greater attraction for pneumococci than normal leukocytes—a fact that points to a difference from the normal in the chemical or physicochemical constitution of the leukocytes in pneumonia. Rosenow notes, too, that the leukocytes of acute appendicitis and of puerperal infection also appear to be endowed with increased powers of phagocytosis.

Continuing the review of the articles concerning the question in hand in an approximately chronologic order, we find that Potter and Krumwiede's[4] results seem to indicate that during the height of the pneumonic attack the leukocytes are less active with respect to pneumococci than normal leukocytes, but during the crisis, and just afterward, the phagocytic power rises and then returns to normal.

Park and Biggs[5] found that leukocytes from different normal persons may vary in their phagocytic power for staphylococci.

Several studies have been made on the relative phagocytic power of the different kinds of polymorphonuclear leukocytes according to Arneth's classification, but with

rather divergent results. Kaplan[6] found that, so far as staphylococci are concerned, the cells with one nucleus are most active phagocytically and those with four, least active. On the other hand, Briscoe[7] and Pottenger[8] conclude that the leukocytes of Arneth's Classes II and III are the most active (staphylococci and tubercle bacilli), while Busse[9] assigns an equal phagocytic value to all classes of neutrophilic leukocytes in health as well as in conditions of inflammatory and postoperative leukocytosis. In so far as these observers used normal blood, it may be assumed that they used mixtures with the same relative number of different leukocytes.

Achard, Raymond and Foix[10] found the eosinophils in normal blood and in the blood of a case of myelogenous leukemia to be without phagocytic activity; the eosinophils in a pleural exudate were phagocytic, however, and in a case of infection with *Filaria loa* Rattan-Launier and Parvu[11] found them markedly active phagocytically.

Ledingham and Bulloch[1] found the polymorphonuclear leukocytes of subnormal activity in native serum in myelogenous leukemia; in chronic lymphatic leukemia, however, the phagocytic power was greater than normal. In a patient with splenomyelogenous leukemia Bushnel[12] found the polymorphonuclear leukocytes less active phagocytically for staphylococci and tubercle bacilli than normal. In myelogenous leukemia Parvu[13] observed that the polymorphonuclear cells were deficient in phagocytic power for typhoid bacilli and staphylococci; the large mononuclears, on the other hand, were active phagocytes. Kentzler[14] also holds that in myelogenous leukemia the neutrophils are below par in phagocytic power. In these cases, however, the question arises whether the actual comparisons made are based on the study of leukocytic suspensions of the same numerical strength. According to Achard, Raymond and Foix,[10] in the leukemias the leukocytes of the normal types have the usual properties but the abnormal cells almost wholly lack phagocytic power.

Shattock and Dudgeon[15] made the following observations: Washed pneumonic leukocytes accomplished more phagocytosis in pneumonic serum than normal leukocytes, while in puerperal streptococcus infection the leukocytes of the puerpera were less active as phagocytes than normal leukocytes in the same serum. As phagocytable objects they used melanin granules from the eye of the horse and colon bacilli. They conclude that the leukocytes from cases of infectious diseases may be more or less active phagocytically than normal leukocytes and recommend for determination of the total phagocytic power of the blood in a given case—hemophagocytic index—a modification of Leishman's technic, but they do not emphasize sufficiently the requirement of working with suspensions holding the same number of leukocytes.

Bayly[16] observed reduction in the phagocytic power of the leukocytes *in conditions of fatigue in tuberculosis.* Eggers,[17] who tested the activity of the leukocytes in pulmonary tuberculosis with respect to tubercle bacilli, pneumococci, streptococci and staphylococci, failed to find any striking deviations from the normal; in advanced cases the activity seemed somewhat less than in the early cases.

Glynn and Cox[18] made extensive comparative studies of the inherent phagocytic powers, with respect to tubercle bacilli and staphylococci, of the leukocytes of three normal persons, of one case of mild staphylococcus infection and of several miscellaneous cases. Their results show that there may be variations in the phagocytic power on the part of leukocytes from different persons and from the same person at different times. In conditions of health such variation is probably nonspecific. Glynn and Cox use the term "cytophagic index" to indicate the relative phagocytic power of leukocytes from a given source, as compared with that of leukocytes from a different source used as the standard, the two mixtures being made with the same opsonic serum; and the term "opsono-cytophagic index" has been introduced to indicate the relative phagocytic powers of the leukocytes and serum of one individual, as compared with the phagocytic powers of the leukocytes and serum of another individual used as the standard. Naturally this index, called by Shattock and Dudgeon the hemophagocytic and by Nikolsky[19] the opsono-phagocytic index, yields information of larger significance than the opsonic index which tells us only the relative amount of opsonic substances in the blood and is determined by finding the amount of phagocytosis accomplished by normal, or presumptively normal, leukocytes under the influence of the serum in question.

The article by Glynn and Cox gives a mass of interesting and valuable technical details. They recognize fully the necessity of conducting determinations of the cytophagic and opsono-cytophagic indexes with numerically equalized suspensions of leukocytes which they, however, attempted to secure by counts of the red corpuscles in the mixtures of washed blood rather than by the more direct, and surely more accurate, method of counting the leukocytes themselves.

In various infectious diseases Achard and his associates[20] find the phagocytic activity of the leukocytes with respect to yeast-cells below normal in the early part of the attack, rising later to normal or higher in case of recovery, but not otherwise. As the investigators made no effort to equalize the number of leukocytes in the mixtures prepared, it is difficult to form any opinion as to the value of their results.

In a case of cystitis caused by pseudodiphtheria bacillus, Rosenow[21] found that subcutaneous injections of the specific vaccine caused a moderate degree of leukocytosis and a definite and specific increase of the phagocytic power of the leukocytes in the mixtures containing their own, that is, the patients' serum.

In certain cases of recurring and chronic erysipelas, Boughton[22] observed peculiar relations between the serum and the leukocytes. In one case in particular, of relapsing and recurrent erysipelas of long standing, which he studied with special care, the opsonic index for the infecting streptococcus was usually much lower when determined with the patient's leukocytes than when determined with the leukocytes of a normal person. There existed some peculiar relation between the leukocytes and the serum of the blood of the patient which reduced the amount of phagocytosis. This result is shown clearly in the following experiment which, like his other experiments of similar nature, was made with leukocytic suspensions of equal density:

Patient's serum + normal leukocytes = 5.5 streptococci per leukocyte. Normal serum + normal leukocytes = 3.13 streptococci per leukocyte. Opsonic index of patient's serum *1.76*.

Patient's serum + patient's leukocytes = 0.76 streptococci per leukocyte. Normal serum + patient's leukocytes = 3.56 streptococci per leukocyte. Index (opsono-cytophagic) of patient's blood *0.21*.

As the phagocytic power of the patient's leukocytes was subnormal in native serum but at par in normal serum, it is evident that the reason of the low phagocytic action of the patient's blood resided in the patient's serum, even though this serum gave a high opsonic index. From the experiments that Boughton made to analyze the mechanism of action of the patient's serum in this case, one cannot determine whether the depressing effect of the serum on the corresponding leukocytes was caused by the absence of some necessary element or by the presence of some inhibitive substance. Boughton found that the addition of a minute quantity of normal serum to mixtures of the leukocytes and serum of the patient's blood promptly raised the phagocytic activity of the leukocytes to normal. Furthermore, the leukocytes of the patient, on being treated with normal serum and then washed with salt solution, would retain normal phagocytic power in the presence of the patient's serum. Hence it does look as if the normal serum did supply some lacking element, and yet there may have been present in the patient's serum an inhibitory substance or quality which normal leukocytes could overcome, but against which the patient's leukocytes were powerless unless in the presence of normal serum or after being treated therewith. That the restorative effect of normal serum was not due to the thermolabile opsonic element is shown by the fact that this patient's serum after being heated was not reactivated by the addition of a small amount of fresh serum. Here, then, is a striking example of reduction of phagocytic power of the leukocytes by obscure changes of a specific character in the homologous serum. It would be strange if conditions like the one described by Boughton do not have a direct bearing on the continuation and progress of the infection. In this particular case the injections of fresh horse serum seemed to have a detrimental effect. Injections of fresh human serum were not given, and it would seem desirable to study the effect of such injections in similar cases.

Rosenow[23] has made extensive studies of the antipneumococcus powers of the blood in several cases of chronic pneumococcus endocarditis. In such cases he finds that there may be considerable variation in the phagocytic power of the leukocytes. At times when there is leukocytosis the phagocytic activity may be greater than normal; more often it is subnormal, especially if the test is carried out with the serum of the same patient as the leukocytes, and occasionally this reduction is limited specifically to the pneumococcal strain causing the infection. In all the experiments bearing on this point as well as on the comparative pneumococcocidal action of the leukocytes, Rosenow used leukocytic suspensions of the same numerical strength, at least as far as the neutrophils are concerned.

Human blood has pneumococcocidal powers. This is easily demonstrable by means of the usual plate method under proper conditions.[24] The pneumococcocidal effect is the result of the conjoint action of the fluid part of the blood and of the leukocytes—by itself either constituent is quite harmless. The first step in this action is opsonification and phagocytosis of the pneumococci; the final step is destruction of the ingested cocci associated with disintegration of the phagocytic leukocytes. Now Rosenow studied particularly the variations in the destructive powers of the leukocytes with respect to pneumococci in cases of chronic pneumococcus endocarditis, and the following in brief are the principal results: While phagocytosis and intraleukocytic destruction of the pneumococci isolated from cases of chronic endocarditis, so to speak, may run hand in hand in mixtures of suspensions of normal leukocytes or of the patient's leukocytes with *normal serum*, this is not always the case in like mixtures with the *patient's serum*. Lowered phagocytic power seems nearly always associated with lowered destructive power, but at times when the phagocytic action of the patient's leukocytes is normal, or greater than normal, there may occur an apparently complete failure of destruction of the pneumococci taken up by the leukocytes in native serum. That is to say, the patient's leukocytes may take up pneumococci readily in native or normal serum, but exercise destructive power only in normal serum. More rarely, this is true of normal leukocytes as well. As illustration I give the results of one experiment:

PATIENT'S LEUKOCYTES

Mixtures	Phagocytosis—figures give average number of pneumococci per leukocyte after 15 min.	Pneumococcocidal action as determined by number colonies on blood agar plates inoculated with equal amounts	
		Immediately	After 24 hours
Normal leukocytes + normal serum..	1.6	30	14
Normal leukocytes + patient's serum.	1.1	35	2500
Patient's leukocytes + normal serum..	1.2	28	15
Patient's leukocytes + patient's serum.	1.4	22	1550

The addition of a small amount of normal serum to the patient's serum restored the phagocytic and destrucive powers of the mixtures with this serum; even the mere washing of the leukocytes in normal serum may accomplish this result, showing conclusively that the serum exercises a definite influence on the activities of the leukocytes which is quite independent of its opsonic influence.

[23] Rosenow: Immunologic and Experimental Studies on Pneumococcus and Staphylococcus Endocarditis, Jour. Infect. Dis., 1909, vi, 245; Immunologic Studies in Chronic Pneumococcus Endocarditis, Ibid., 1910, vii, 429.

[24] Rosenow: Jour. Infect. Dis., 1910, vii, 440.

The failure of intraleukocytic disintegration to take place in the patient's serum seems to be specific for the infecting pneumococcus, at least in some cases. In attempting to analyze this phenomenon, Rosenow made some experiments in which he used endocarditis pneumococci that had been "sensitized," i. e., previously treated with serum at 37 C. for ninety minutes and then washed. In this case normal leukocytes destroyed the pneumococci sensitized in the patient's serum just as well as those sensitized in normal serum, hence their occasional lack of destructive action in the full presence of the patient's serum must be due to the effect of that serum on the leukocytes. With respect to the patient's leukocytes, it was found that at times they failed to destroy cocci whether sensitized in normal serum or in the patient's serum—hence were lacking in some quality possessed by normal leukocytes—whereas at other times they would destroy only those pneumococci that had been treated with normal serum. These facts point to the existence in normal serum of a substance or quality which promotes the intraleukocytic disintegration of pneumococci. In cases of chronic pneumococcus endocarditis, lowering of the destructive power of leukocytes may be due to a deficiency of this substance or to the presence of a neutralizing substance. In Rosenow's cases, the occurrence of joint involvement and other complications was preceded by a fall in the phagocytic and destructive powers of the blood toward endocarditis pneumococci and succeeded by a rise. These observations also help us to understand that specific inoculations, even though they may increase temporarily the amount of opsonin in the blood, nevertheless may be without any good effect in cases in which leukocytes have lost the power to destroy pneumococci. In such cases, injections of fresh homologous serum would seem indicated.

In a study of the anti-infectious power of infants' blood, Tunnicliff[25] finds that at birth the phagocytic activity of the leukocytes is a little below that of the leukocytes of normal adults so far as streptococci, pneumococci and staphylococci are concerned. During the first months of life the activity falls, but soon a rise begins and the adult standard seems to be reached at about the third year. The opsonic power of the serum describes a similar curve. The low phagocytic power of the leukocytes in infancy as compared with later years would seem to be inherent in the leukocytes because it is demonstrable in phagocytic mixtures prepared with the serum of adults as well as with the serum of infants. Tunnicliff's work indicates, then, that during the first and second years of life the anti-infectious powers of the blood for the bacteria mentioned as measured by the opsonic power of the serum and the phagocytic power of the leukocytes is far below that of adult blood.

Tunnicliff[26] has determined also that the leukocytes in exudates, induced by injections of aleuronat (gluten-casein) suspension in guinea-pigs and dogs, are more active phagocytically than the leukocytes in the blood of the identical animals. To be more specific, in comparable mixtures, using suspensions holding the same number of carefully washed polymorphonuclear leukocytes, the leukocytes of the exudate not only take up a larger number of bacteria (pneumococci, streptococci, tubercle bacilli), but a larger number of leukocytes engage in phagocytosis than in the case of the leukocytes obtained from the blood. Tunnicliff[27] furthermore has shown that, as a rule, there is an increase in the phagocytic power of the leukocytes (cytophagic index) in favorable cases of pneumonia, both before and after crisis. In severe cases the phagocytic power usually is diminished, but rises above normal as improvement sets in. This variation in the phagocytic power of the leukocytes is not specific for pneumococci but is demonstrable also with streptococci and staphylococci. And pneumococcocidal experiments by means of the plate method showed the variation in the phagocytic power to be associated with corresponding and parallel variation in the destructive power. Similar non-specific variations with respect to the leukocytes were observed in severe cases of scarlet fever. In a patient with chronic articular rheumatism there resulted an increase not only in specific opsonin but also in the phagocytic power of the leukocytes after injections of killed streptococci, obtained originally from the patient's tonsil, and this increase in the total phagocytic power of the blood was associated with an increase in the streptococcocidal power of the blood, using normal blood as the standard.

SUMMARY

In determination of the comparative phagocytic power of leukocytes, suspensions prepared under like conditions and holding the same number of leukocytes must be used. Results obtained without these conditions being satisfied are of doubtful value.

It seems that the inherent phagocytic power of the leukocytes of the blood may be subject to some variation, with respect to certain bacteria at least, even in persons in apparently perfect health. Further study on a more extended scale is needed. In the meantime, the idea that the source of the leukocytes for estimation of the opsonic index is wholly immaterial cannot be sustained.

At birth, the leukocytes are somewhat less active phagocytically than in the adult; they grow less and less active during first months of life and then more active, the adult standard for streptococci, pneumococci and staphylococci being reached about the third year (Tunnicliff). On this account, as well as for other reasons, the opsonic index in infants should be determined with leukocytes and serum of infants of the same age as the standard.

There is no conclusive evidence that the different kinds of neutrophils (according to Arneth's classification) differ in phagocytic activity.

There are indications that in myelogenous leukemia the neutrophil leukocytes are below normal in phagocytic power, but further comprehensive studies are necessary in order to obtain conclusive results.

The phagocytic power of leukocytes has been found to be greater than normal, with respect to pneumococci, streptococci and staphylococci, in pneumonia, scarlet fever and other conditions in which there is acute leukocytosis and the outlook is favorable. In pneumonia the leukocytes may be more resistant to heat than normally, they may have greater attraction for pneumococci, and they may take up pneumococci too virulent to be taken up by normal leukocytes (Rosenow).

In pneumonia and in scarlet fever, the destructive powers of the leukocytes for pneumococci and streptococci run parallel with the phagocytic power. In severe cases of pneumonia and scarlet fever, the phagocytic and destructive powers of the leukocytes may be lower than normal.

[27] Tunnicliff: On Variations in the Phagocytic and Coccidal Power of the Blood in Pneumonia and Scarlet Fever, Jour. Infect. Dis., 1911, viii, 302.

In recent exudates the leukocytes are more active as phagocytes for streptococci, pneumococci, and tubercle bacilli than the leukocytes of the corresponding blood.

The exact causes of the increase in the activity of the leukocytes are not known; it has been suggested that in pneumonia and other acute diseases, in which there is leukocytosis, the increase in activity is owing to the predominance of young leukocytes.

In certain chronic infections, notably chronic pneumococcus endocarditis and chronic erysipelas, the phagocytic activity of the leukocytes may be either above or below normal; at times there may occur a distinct fall in their phagocytic power, which may be specifically limited to the infecting microorganism or observable only in the native serum or both. While the reasons for this fall are yet obscure, it appears to be related closely to changes in the fluid part of the blood because small quantities of normal serum may correct the condition, and so may the mere soaking of the leukocytes in normal serum. What is said of the phagocytic activity appears to apply fully to the processes that lead to intraleukocytic disintegration of the pneumococci in chronic pneumococcus endocarditis. Hence it may be concluded that the fluid of the blood, independently of its opsonic function, directly influences the phagocytosis and intraleukocytic destruction of certain bacteria.

We may say, then, that in acute as well as some chronic infections with pneumococci and streptococci, and possibly also with other bacteria, a real grasp of the specific anti-infectious powers of the blood of the patient is obtainable only by the determination of the combined phagocytic powers of the leukocytes and serum of that blood and of their combined destructive action. In chronic infections, this determination should be made with reference to the infecting strain. Here, especially, the opsonic index alone may be misleading as it may be normal or above normal, and yet the leukocytes of the patient may have less phagocytic power, and, associated therewith or independently thereof, less destructive power than normally.

So far, specific variation in the leukocytic activities with respect to the infecting strain have been observed in infections of long standing only. Such seemingly very special adaptations naturally require time for their development. Further studies along these lines are indicated because the results may lead to a still better understanding of such infections and their treatment.

ADIPOSITY OF THE MAMMARY GLANDS *

J. R. GUTHRIE, M.D.
DUBUQUE, IA.
AND
HENRY ALBERT, M.D.
IOWA CITY, IA.

There are no more interesting and few more mysterious questions in the field of physiologic research than those concerned with the problem of fat metabolism. As a pathologic process, an abnormal fatty condition has been discovered in various organs; one of us (Guthrie) reported a case of necrosis (with fatty change) of the kidney, in the Section on Surgery of this Association at its New Orleans meeting. Reported cases of abnormal adipose conditions of the mammary glands are rare.

Cases of unusual non-neoplastic enlargement of the mammary glands have been reported from time to time as examples of diffuse idiopathic hypertrophy of these structures. One of us (Albert[1]), in reporting a case of this kind a year ago, also reviewed the descriptions of the sixty-nine other cases which had been previously reported. Clinically, cases of idiopathic hypertrophy may be divided into (1), those associated with gestation and (2), those not associated with gestation, most of which are closely related to puberty. Pathologically, the hypertrophied glands are found to consist essentially of a hyperplasia of both the glandular and connective tissue-elements—the hyperplasia of the former predominating in idiopathic gestation hypertrophy, whereas the enlargement of the idiopathic puberty hypertrophy consists principally of fibrous connective tissue.

In the description of the sixty-nine cases referred to,[1] mention is made in only three of the presence of an excess of adipose tissue. Robert and Ammesat,[2] in describing a case of enormous hypertrophy of the mammary glands, stated that microscopic examination indicated an increase especially of adipose tissue.

J. C. Warren,[3] in referring to a case of idiopathic puberty hypertrophy, states that "microscopic examination showed the presence of fat, loose fibrous tissue and atrophied gland-structures."

Beatson,[4] under the title "Hypertrophy of the Female Mamma," refers to the pathology as follows:

> After removal both mammæ presented on section much the same appearance. They were seen to be largely composed of fatty tissue, as if the cause of their excessive size was due to an abnormal growth of fat (lipomatosis). Microscopic examination, however, of the breast-tissue did not support this view. Sections of it showed the glandular elements of a normal breast in a resting condition, but the number of acini seemed to be fewer than normal, while the intra-acinous fibrous tissue was in excess and very dense in character, though scattered through it were spaces filled with a considerable amount of fat. From the appearances observed, it seems very probable that the fat and fibrous tissue went to make up a large part of these hypertrophied mammæ.

The photomicrographic reproduction which accompanied the article suggests that it consists principally of fat.

The case which we are reporting is one in which the enlargement of the mammary glands is due almost entirely to adipose tissue.

REPORT OF CASE

History (Taken May 17, 1910).—The patient, a woman, aged 24, was born in Iowa of German parentage. She is 5 feet 2 inches tall and weighs 164 pounds; is rather stoutly built and fleshy, but not fat. Father's age is 49 and mother's age 45; both are living and well. She has five brothers and four sisters, all living and well. In none of the other members of the family has there ever been any undue enlargement of the mammary glands. In fact, all the sisters, one of whom is more fleshy than the patient, have very small "flat" breasts. Patient began to menstruate at the age of 11. At this time occurred the usual slight enlargement of the breasts. The menstrual periods have always been more or less irregular, being often absent for a period of three or four months.

4. Hypertrophy of the Female Mammæ, Edinburgh Med. Jour, 1908, New Series, p. 525.

Present Illness.—When patient was 16 years of age she was sick for three weeks with a severe attack of mumps and what was diagnosed as malaria. Near the beginning of this period of illness she suddenly developed, one night, a severe dull aching pain in both breasts, accompanied by some swelling but no redness. Local applications and bandages were applied, but had no effect on the process. During the following six years the glands gradually grew in size until, at the age of 22, they were about the size of a cocoanut and only slightly painful. At that age she was married (March 21, 1908). From the time of marriage to the time of beginning of pregnancy (about five months) the breasts continued to remain about the same as they had been for some time previous to marriage. After the beginning of pregnancy, the mammæ began to enlarge rapidly, but were for some time no more painful than usual. At the end of the fourth month of pregnancy, they became very painful and remained so during the pregnant state. During the sixth month patient had severe edema of the feet and eyelids and was confined to her bed for several weeks. During this time there was an occasional slight hemorrhage from the uterus. At the end of the seventh month of gestation, the physician found it necessary to produce an abortion to save the life of the patient. The child which was delivered is now 14 months old, weight 22 pounds and appears perfectly well. A small amount of milk appeared from the nipples during the first two days after the delivery of the child. The child could not be suckled, however, because of a flattening out of the nipples due to the excessive growth of the glands. Patient made a good recovery from the illness which produced the edema of the feet and eyelids. After the termination of pregnancy the glands became more soft and the pain less intense, although they remained of about the same size as they were during the last few months of gestation, which is practically the same as they are at the present time. During the past three months the breasts have become especially painful, the pain being most severe in the outer, upper quadrant of the glands. The last and only pregnancy was terminated about fourteen months ago. Since that time the menses have appeared quite regularly. Patient was admitted to the University Hospital May 16, 1910. (Hospital No. 9839.)

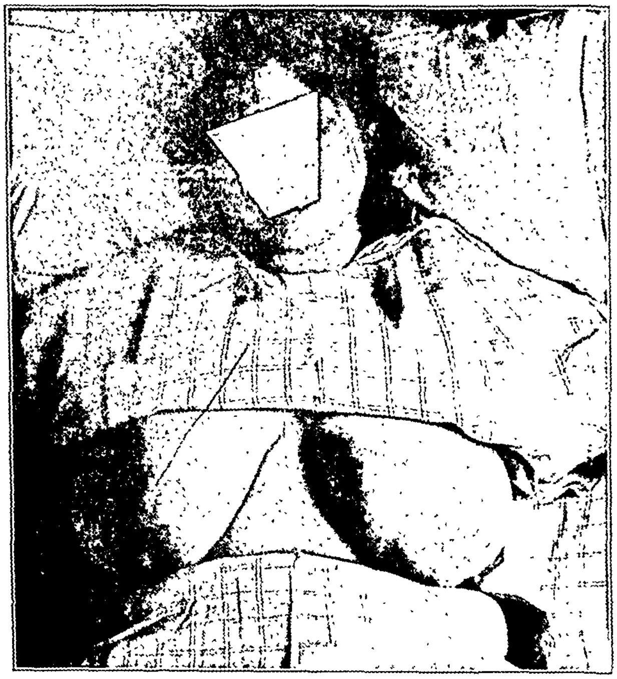

Fig. 1.—Patient with adiposity of mammary glands. From a photograph.

Physical Examination of Breasts.—Both glands were rather uniformly enlarged, more or less spherical in shape and hung down so that the most dependent portion of each was on a level with the umbilicus. The right gland (gland-substance) measured 7½ inches from base to nipple; the left, one-half inch less. On the other hand, the left exceeded the right in circumference (greatest), that of the former being 18 inches and of the latter 17½ inches. The nipples appeared as very slight elevations (about one-twelfth inch) on the lower and anterior surface of the glands. The areolæ, which were each about 2¾ inches in diameter, were well pigmented and quite sharply outlined. The skin covering the glands was smooth and quite uniformly stretched over the underlying tissue. The breasts were rather soft in consistency. The presence of quite firm nodules suggested the presence of localized areas of glandular tissue embedded in a mass of adipose tissue. The upper, outer quadrant of the right gland was of a more uniformly firm consistency than any other portion. On account of the severe and continually increasing pain experienced by the patient during the preceding three months, it was decided to amputate the breasts, which was accordingly done by one of us (Guthrie), May 17, 1910.

Operation.—The patient was prepared in the usual manner and a complete amputation of both breasts performed. The glands appeared, from ocular examination, to consist entirely of fat, and hence the pectoral muscles were left undisturbed. The wound was closed with silkworm sutures and a gauze drain placed in the lower angle of each wound.

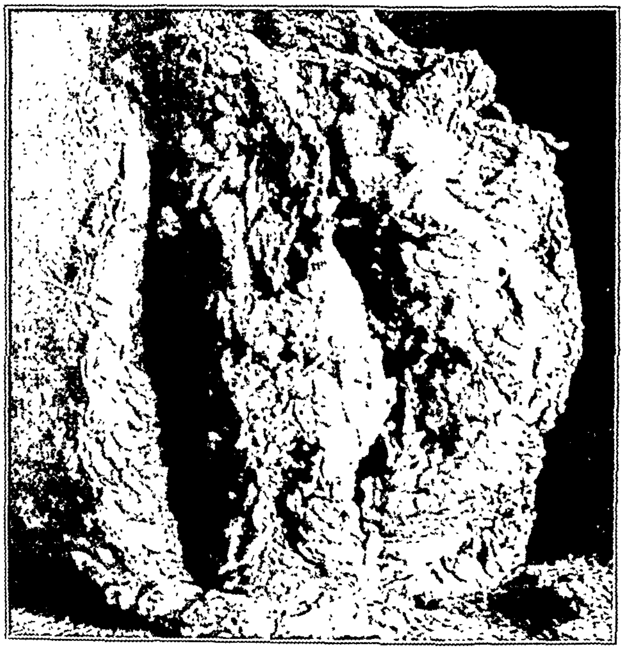

Fig. 2.—Base of left gland, incised, showing lobules of adipose tissue, between which are thin strands of connective tissue.

Postoperative History.—The patient followed a normal course for three days when there developed a mild temperature, the result of a slight infection of the right wound with a rather profuse purulent discharge. The wound was opened, drainage continued a few days, and a reasonably rapid convalescence followed. The patient had no distinct chill at any time.. The discharge was like that frequently seen in very fat abdominal walls with mild infections. Otherwise she made an uneventful recovery and left the University Hospital June 24, 1910. On Feb. 7, 1911, she wrote that she was perfectly well; that she had gained 30 pounds since leaving the hospital, her weight at that time being 150 pounds, and that she could then perform the work of caring for her home. On April 20, 1911, she reported that her weight had increased to 160 pounds, i. e., within 4 pounds of her weight prior to the operation. Monthly periods were regular and free from pain. Her recovery from pain and the incapacitating weight of the gland was complete and she is able to resume entirely her usual work.

Gross Pathology.—The amputated glands together weighed 10¼ pounds, the right 5½ pounds and the left 4¾ pounds. The shape, dimensions and surface contour of the glands changed considerably after they were removed from the body.

The substance of the glands was found to consist of adipose tissue, with the exception of a few strands of connective tissue running here and there between lobule-like areas of the fatty structure.

Pathologic Histology.—A section cut from almost any part of the gland presented the microscopic appearance of ordinary adipose tissue. This was continuous with what appeared to be the subcutaneous fat. The connective tissue was of the normal, fully developed fibrous type. The larger strands of connective tissue were found to contain a few small gland acini lined by a single layer of cuboidal epithelial cells and representing, apparently, the gland elements in a resting stage.

DIFFERENTIAL DIAGNOSIS

The condition which we have described and which we have chosen to designate as "adiposity of the mammary glands," needs to be differentiated from the following processes:

1. An excessive size of the mammary glands as a part of *general obesity.* In such conditions, the breasts, although containing a large amount of fat, still have their real glandular portion quite well circumscribed and relatively free from fat. In the case which we describe, there was no portion which, to the naked eye, contained any evidence of glandular elements. Furthermore, the patient in question, although rather fleshy, had apparently but little more subcutaneous adipose tissue than the average person. Then, too, her glands increased in size and tenderness at a time when there was no increase in her general body weight.

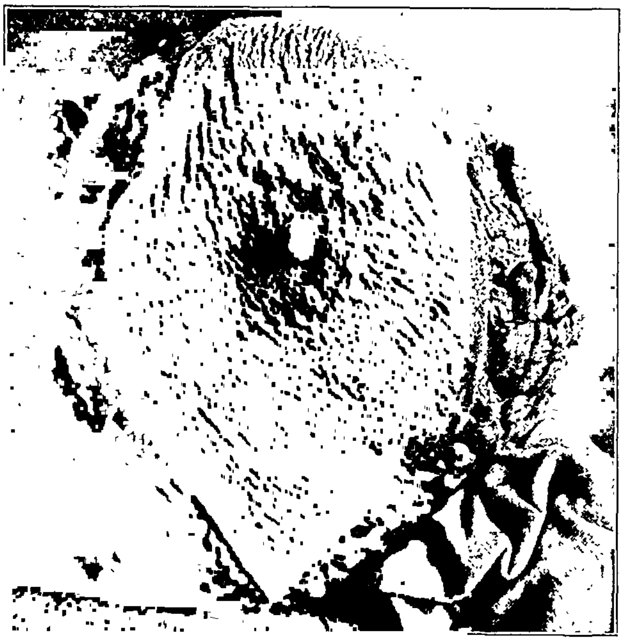

Fig. 3.—Left gland showing lobules of adipose tissue beyond the edges of the skin which has been contracted and wrinkled by the formaldehyd preserving fluid.

2. *Idiopathic hypertrophy,* consisting of a hyperplasia of the connective tissue or the glandular elements. Before the glands were amputated, we believed that we were dealing with a case of this kind. We do not believe that it is possible to differentiate between the two conditions until an incision into the gland and a recognition of its structure is made.

3. *Diffuse lipoma.* A tumor, although often quite diffuse, is more or less circumscribed, tending to push the real glandular structure to one side. In our case there was no suggestion of circumscription and the gland acini were quite uniformly distributed—embedded in the slight amount of connective tissue throughout the gland.

PROGNOSIS

In each of the three cases already cited from the literature of idiopathic hypertrophy of the mammary glands, which we regard as probably cases of adiposity, the glands were amputated and amputation was followed by recovery, as in our case. We have therefore no data as to the prognosis in case amputation is not made.

CONCLUSIONS

1. The condition which we have described, representing an unusual enlargement of the mammary glands and consisting almost entirely of adipose tissue, we have chosen to designate by the term "adiposity of the mammary glands."

2. Of the seventy cases of diffuse idiopathic hypertrophy of the mammæ of which we have found a record in the literature, in one mention is made of the fact that the enlargement was due principally to adipose tissue; in two others attention was called to the large amount of adipose tissue present. We believe that the one, certainly, and the other two, probably, were cases of adiposity of the breasts.

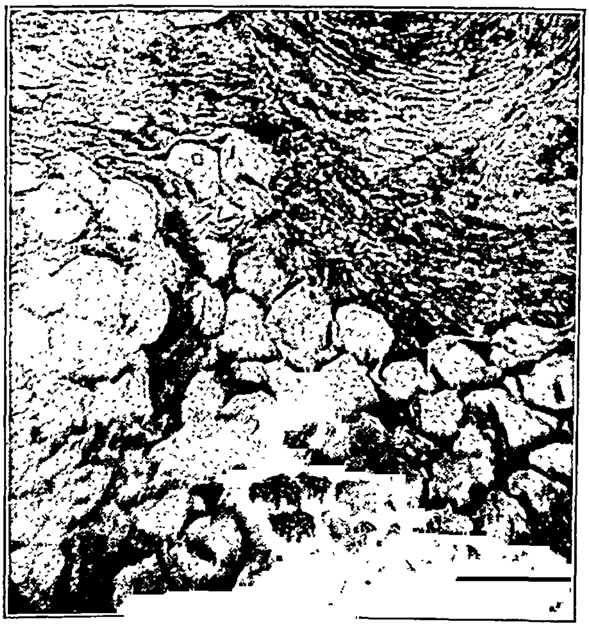

Fig. 4.—Section from piece of left gland showing adipose tissue adjacent to one of the larger strands of connective tissue, in which were found a number of gland acini presenting practically the normal size, shape, structure and arrangement. The mamma consisted almost entirely of adipose tissue of normal appearance.

3. We believe that it is advisable to make more general use of the term "macromastia" to denote enlargement of the breasts due to any cause, and to differentiate between the terms "hypertrophy" and "adiposity," according to whether the enlargement is due to glandular (and possibly also connective) tissue on the one hand, or adipose tissue on the other.

Municipal Health.—No community is so poor that it can afford to permit typhoid for the lack of a filter, or inefficient children for the lack of good schools, or criminals for the lack of playgrounds, or wayward girls for the lack of protection, or exploited childhood for the lack of a factory inspector, or industrial accidents for lack of a compensation law or an insurance system.—Devine in "Misery and Its Causes."

THE TREATMENT OF CERTAIN OBSTRUCTIVE BENDS OF THE INTESTINES DUE TO ABNORMAL MESENTERIC ATTACHMENTS AND INADEQUATE PARIETAL SUPPORT *

FRANKLIN H. MARTIN, M.D.
CHICAGO

There are four important portions of the intestinal tract that suffer notable distortion and lead to pathologic results due to an anomalous condition of the mesenteric attachments and inadequate support of the abdominal parietes, viz., the duodenum, the terminal portion of the ileum, the appendix vermiformis and the sigmoid.

The distortion usually occurs as a result of the two principal causes named, but may occur in a less aggravated form with only one of the two causes acting. In a recent paper I dwelt on these causes as they especially affected the terminal portion of the ileum, and the facts given there as an explanation of the distortion occurring at that portion of the intestinal tract apply in principle to the other regions enumerated. In this paper I wish to note briefly a line of postoperative treatment which I consider rational and which has been successfully pursued in a number of the terminal ileum variety of distortions commonly known as the "Lane kink" (Fig. 1).

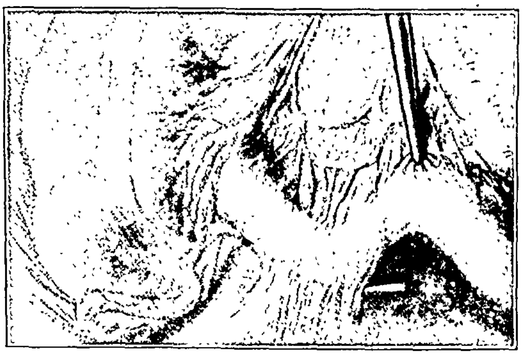

Fig. 1.—A kink with adhesions. Not a marked type. Picture borrowed from C. H. Mayo.

The Lane kink is a term applied to a pathologic bend of the terminal six inches of the ileum. It is manifested by an acute angle of that portion of the bowel complicated by a thickening of its mesentery and the adhesion of the two arms of the angle together, to surrounding intestinal coils, and to its own mesentery in which it is frequently rolled, the whole condition eventuating in more or less intestinal stasis.

I have concluded that the kinking of the ileum within 4 inches of its cecum attachment instead of elsewhere is due to the fact that the ileum at its termination in the large bowel possesses an extremely short mesentery, viz., from 1 to 2 inches. Given this comparatively fixed portion of the compressible tube, there are two factors which lead to its distortion, (a) a too movable or displaced large bowel, and (b) an abnormal disposition of the remaining portion of the small bowel or other viscera.

Adhesions occur from (1) extension of infection from infected appendix in both male and female, and the uterine appendages in the female; (2) from friction of the opposed serous membranes from violent mechanical action resulting from the factors causing the distortion; (3) rarely from direct migration of bacteria through the violated tissues of the intestines.

The different conditions I have observed accompanying pathologic kinks of the last 6 inches of the ileum are as follows:

A. Extreme prolapse of cecum and ascending colon.

B. Extreme prolapse of the stomach with transverse colon prolapsed beneath the stomach, the small intestines filling the pelvis and lower abdomen underneath the stomach and colon, resulting in a definite right angle kink of the ileum near its attachment to the cecum.

C. A condition in which both cecum and small intestines are prolapsed, and in which a tendency to general visceral prolapse is present, resulting in a variety of kinks in the last 6 inches of the ileum, owing to pull on its short mesentery, the shape and direction of the bend depending on the particular influence exerted on it by the abnormal position of the viscera surrounding it.

D. The kinks or bends are in my opinion due, therefore, to a decided displaceability, not only of the cecum, but of all the viscera surrounding the last three inches of the ileum, traumatizing it by undue pulling on its distal end in the case of the cecum, on its proximal end in the case of the balance of the ileum, or by pressing on it and its attached mesentery, and grinding their opposing surfaces together in case of marked displacement of the superimposed viscera, such as the right kidney, the liver or stomach.

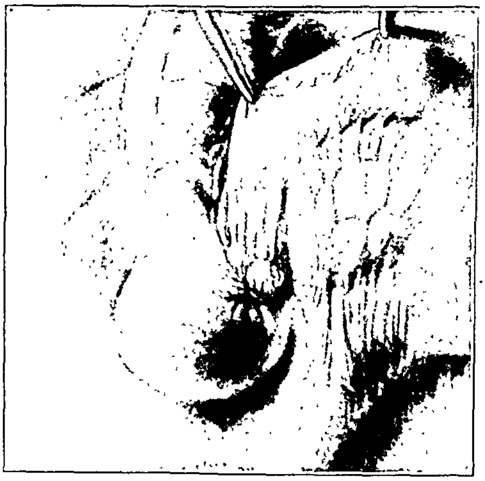

Fig. 2.—Same as Figure 1, with kink obliterated. (From C. H. Mayo.)

The causes leading to a tendency to general visceral ptosis, which is such a strong factor in the production of this obstructive bend, are naturally two in number, viz., congenital and acquired.

The congenital defects are found (a) in the failure of early blending of the peritoneal layer with the parietes which results in the normal individual with an adequate fixation of the stomach, the liver, the spleen, the pancreas, the duodenum, the ascending and descending colon; (b) in a failure of normal development of the muscular parietes of the abdomen and the strong supporting fascia which aid in retaining the viscera at their normal levels in the perpendicular human being.

The acquired defects are brought about by acute or chronic diseases which leave the individual without normal abdominal muscle support, and diseases which deprive the individual of normal fat deposits in the parietes and about the viscera in the abdominal zone.

---

* Read in the Section on Obstetrics and Gynecology of the American Medical Association, at the Sixty-Second Annual Session, held at Los Angeles, June, 1911.

As the same treatment applies, with a few obvious variations, to the pathologic bends in the other portions of the intestinal tract after operative correction, and to the general management of abdominal prolapse, I shall describe the treatment as I have carried it out in the management of the Lane kink. I shall not enter into a detailed discussion of the methods of treating this condition, as described and carried out by Mr. Lane, more than to say that I can hardly conceive of a case in which short-circuiting with the lower bowel or the more radical operation of removing the colon, as advocated and carried out by him, can offer a more certain cure (and certainly it is attended with greater risk) than can be obtained by the less radical procedure that I am to describe (Fig. 2).

Very often in the past, the kink at the terminal end of the ileum was discovered in the course of an appendectomy or other exploratory abdominal operation. Finally, the significance of an intestine nearly obstructed by an acute bend and maintained so by strong peritoneal adhesions was forced on the attention of one more thoughtful than the rest, and he was fortunately unconventional enough to say to us that we had been overlooking something. Now, we not only find this important pathologic condition in a large number of cases, but we have learned to realize that it accounts for uncured appendicitis and some of us have demonstrated it by reoperating on our patients.

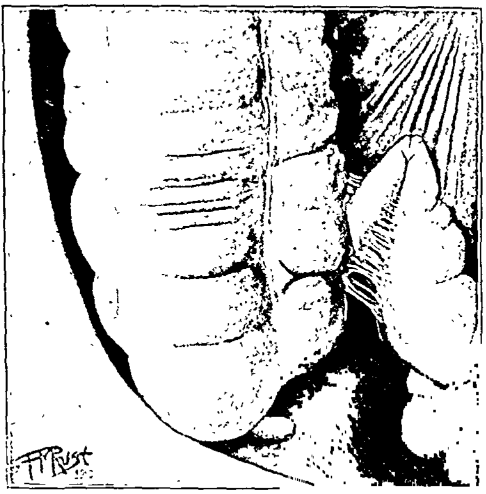

Fig. 3.—A typical Lane kink drawn from one of author's cases.

In the beginning we were satisfied (as we knew nothing else to do) to incise the adhesions, straighten out the bowel, tuck a mass of omentum in the uncovered space, close the abdomen, and as soon as the same condition reoccurred which caused the difficulty, viz., the patient assuming an upright position and pursuing his daily labors, the pathologic kink returned with all its symptoms. The method I have pursued is as follows:

Laparotomy through a right rectus incision. Treatment of any concurrent diseased condition after careful exploration of the abdomen. Separate, especially, the adhesions about the sigmoid and straighten out any acute bends of the intestines, as it is the acute bend in a disadvantageous position made permanent by adhesions which gives rise to symptoms; bring up the head of the cecum with the terminal portion of the ileum. If it is covered with an adventitious membrane (the Jackson veil, Fig. 5, B), as it frequently is, this should be torn through and the underlying structures freed from it. The ileum should then be made taut to reveal the maintaining adhesions and these adhesions carefully divided with a knife, or when particularly frail, with sponge dissection. This releases the intestine and it will unroll (as it is frequently twisted) and straighten out. The patient should be in Trendelenburg position during the operation. After the bend is freed, the cecum and the attached ileum are replaced in their normal positions. These new positions will frequently be much higher than the position in which they were found. The omentum is then spread over the parts treated and the abdomen closed.

Before the last procedure, in severe cases, the radical treatment that has been carried out by Mr. Lane and his followers has been to short-circuit a portion of the ileum above the seat of the obstruction to some portion of the lower bowel, and in extreme cases remove the colon. This procedure has been carried out on the theory that the kink will reoccur at the same portion of the ileum as before, and that the colon has been rendered worse than functionless by the same inherent vicious condition in the dynamics of the abdomen that has produced the kink.

As previously stated, I believe that these pathologic kinks occur as a result of the fact that the portion of the intestine with short mesenteries, the seat of the bend, has been unduly pulled on by the intestinal tube immediately proximal and distal to it, because of abnormal looseness of attachment of these portions to the parietes or the grinding and pressure of overriding, superimposed, prolapsed viscera, and to lack of abdominal support. Therefore, I believe that the rational procedure necessary to prevent a recurrence of the bend is to support the proximal and distal portion of the intestine adjacent to the corrected kink by peritoneal fixation if practicable and by reinforcing, temporarily at least, the abdominal wall by supports; and then by a course of gymnastics, postural treatment and forced feeding, correct permanently the mechanical defects.

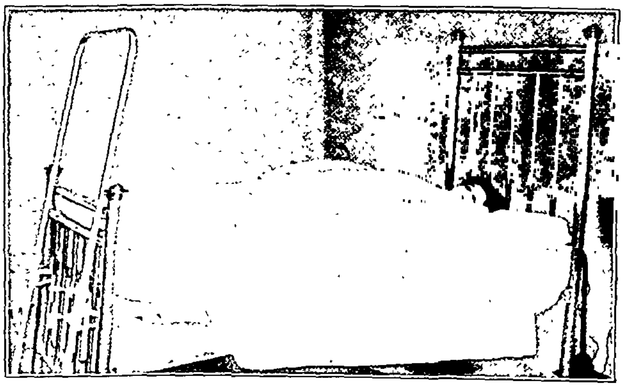

Fig. 4.—Mechanism for supporting the bed in Trendelenburg position. Author's case.

For some time I have endeavored to execute systematically the following procedure: (a) replacement of the adjacent pulling viscera, aided by the Trendelenburg position; (b) the application of a snugly fitting adhesive-plaster abdominal support over a reinforcement, immediately above the pubis, of a combination pad; (c) the transference of the patient from the operating-table to a bed with a 15-degree Trendelenburg inclination (Fig. 4); (d) a careful regulation of the food-supply as convalescence will allow until forced feeding is established; (e) with convalescence from operation, a careful application of a permanent abdominal support or corset to be worn during the day, always applied with patient in steep Trendelenburg; (f) systematic gymnastics of the abdominal wall for fifteen minutes twice a day, night and morning, with patient in Trendelenburg position without the abdominal support; (g) systematic regulation of the diet after convalescence, with the object of increasing flesh and depositing in all portions of the individual a padding of normal fat.

In the operation, careful observance should be made to ascertain, when a prolapsed cecum is one of the etiologic factors of the bend, if the prolapse is due to a lack of normal blending of the ascending colon with the posterior parietes. If the blending has failed to occur, the defect may be remedied by attaching the outer border of the ascending colon to the peritoneum of the parietes, thus imitating Nature's way of obliterating the mesentery in embryo. F. Gregory Connell[1] utilizes a portion of the Jackson membrane (this membrane frequently being present where the ascending colon has failed to attach) as a means of suspending the head of the large bowel, by including a twisted portion of the upper end of the membrane which has been detached, in the muscles of the abdominal wall in closing the parietal wound (Fig. 5, B and C).

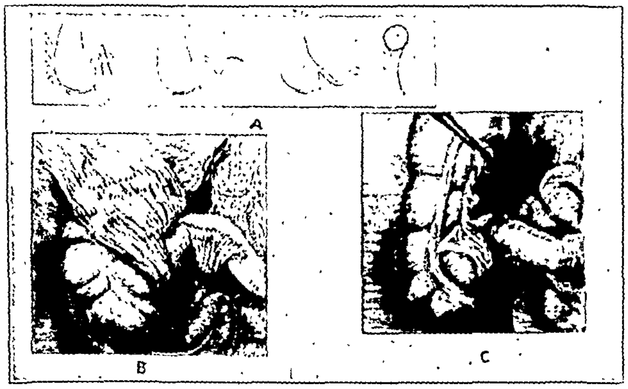

Fig. 5.—(A) Types of Lane kink, from Lane's article. (B) A kink of the terminal ileum covered with a Jackson membrane (one of Connell's cases). (C) Method of utilizing the Jackson membrane in fixing the cecum at its normal level. (Same case from F. Gregory Connell.)

In a large percentage of the cases in which peritoneal blendings have failed to develop, however, there is such a universal visceral prolapse that it is futile to attempt to cure them by any form of "pexies," and I therefore carefully replace the organs, the force of gravity in the Trendelenburg position aiding, and depend on the week in bed with the lowered head and closely fitting bandage to retain the viscera at their normal level until convalescence begins.

Then comes the "tug of war" in the management of these cases. The perpendicular position of the patient with the resumption of routine duties will immediately, without the most strenuous efforts to counteract the effect, precipitate a relapse of the condition of kink with its attending disasters of local distress, stasis, toxemia and obscure anemias, by bringing into play the very factors that caused the difficulty originally.

The patient is fitted with a stout linen bandage constructed in such a manner that it definitely and adequately supports and uplifts the contents of the lower abdomen. These supports can be made after some general pattern (Figs. 6 and 7A), but each one must be carefully fitted by an expert bandage-maker and the surgeon must know that they accomplish the work for which they are intended. The support must be constructed, too, in such permanent shape that its reliability can be depended on. This bandage in women can be replaced later by a properly constructed corset (Fig. 7B).

With this abdominal bandage, the patient may be allowed to assume the perpendicular position and to walk.

Each night before retiring, the patient assumes a position on a Trendelenburg table, improvised or otherwise, with a 15° to 20° inclination and the bandage is removed for the night. After its removal the abdominal muscles should be exercised for fifteen minutes. In a sanitarium or hospital (Fig. 8), this can be superintended by an attendant. At home it can be done by a member of the family. In some cases, if the patient is sufficiently impressed with the necessity for thoroughness, he or she can be trusted to carry out the treatment. The object to be accomplished is the voluntary exercise of the muscles by contracting them against an applied resistance. This resistance can be applied by the hands of the masseur, the patient's own hands or some mechanical apparatus, such as a vibrator or a large wooden ball which can be moved about over the abdomen by the patient. Each portion of the abdomen should be systematically covered and all the muscles made to contract against the applied resistance. An inexpensive home treatment is the tossing or elevating of the ball by successively contracting different portions of the lower abdomen as the ball is moved from place to place.

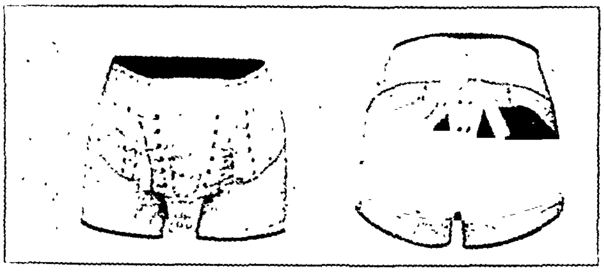

Fig. 6.—Types of bandages employed suitable to both men and women.

The patient then retires after the fifteen-minute exercise of the abdominal muscles combined with the postural treatment. On rising in the morning, before the bath, the same posture is assumed and the exercise repeated. Then after the bath, with the patient still in Trendelenburg position, the abdominal support is applied for the day.

Systematic feeding with the object in view of increasing the flesh, especially the normal deposit of fat of the patient, should be our principal aim in the treatment of these individuals. As a rule this is not a difficult matter after the partial obstruction of the intestines has been removed by the liberation of bands of adhesions and kinks of the intestine which have given rise to the intestinal stasis. Very often a normal, well-selected diet of nourishing food will be readily assimilated and this can be supplemented by cream and, if the bowels are still inclined to require some additional stimulation, a liberal allowance of pure California olive oil may be added, if it is not objectionable to the taste of the individual, the oil aiding in the increase of fat accumulation and its excess acting as a laxative.

If the patient, with the exercise that should be indulged in, is unable to digest a normal liberal diet at the beginning, a careful regulation of predigested foods should be made or the administration of smaller quantities of undigested staple foods at more frequent intervals. I can conceive how it might occasionally be necessary to pursue the careful diet-regulation of the Weir Mitchell method of forced feeding, although in the class of cases under consideration I have not found it necessary. My patients have voluntarily sought a liberal normal diet, and their digestions have been equal to the new demands on the digestive organs.

---

[1] Surg., Gynec. and Obst., November, 1911.

The result of this systematic treatment I have outlined, it seems to me, must be obvious. The liberation of the acute kinks of the small intestine and the separation of adhesive bands and adhesion of surfaces of intestine to each other and to their mesenteries, as well as other soft parts, makes patulous hitherto obstructed or partially obstructed intestines (Fig. 9).

Replacing these restored viscera to their normal positions, together with all other displaced viscera which may have influenced their distortion, by means of a laparotomy and then placing the patient while convalescing on an inclined plane in bed, in order to utilize gravity to maintain the corrected viscera at a normal level while healing, prevents immediate relapses, and normal healing temporarily prevents relapse.

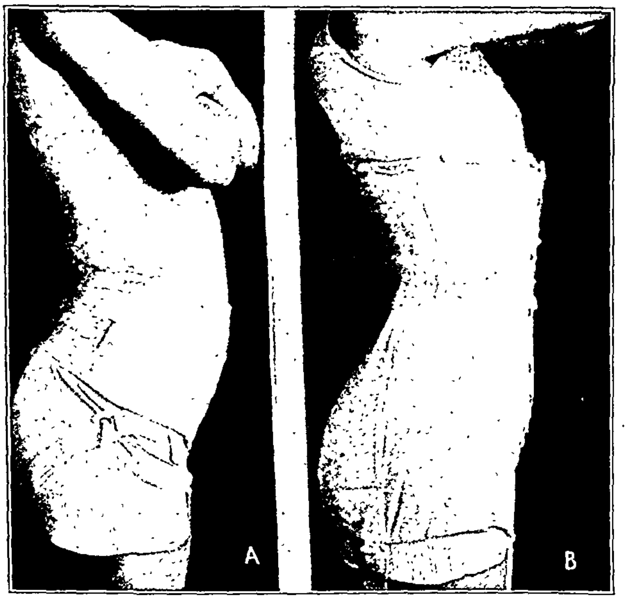

Fig. 7, A.—A type of bandage employed immediately after patient leaves her bed. Worn while patient is in upright position.

Fig. 7, B.—The type of corset that may be used as a substitute for bandage as the patients are convalescing. Author's case.

The application of an adequate day-time bandage as soon as the patient leaves the bed and is prepared to assume the perpendicular, the systematic exercise of the abdominal muscles night and morning while the patient is in steep Trendelenburg, not only restrains a pulling of the otherwise loose viscera on the terminal ileum, but affords an opportunity of restoring tone to the lax and inadequate abdominal muscles and fascia.

While the forced feeding places a zone of fat beneath the parietal peritoneum, a substantial layer of fat between the two leaves of all mesenteries restores the fat in the kidney spaces, reinforces the omentum and thereby stiffens and shortens the peritoneal supports everywhere, pads the loose spaces of the abdomen and actually assists in rendering taut and supportive the whole abdominal content.

This treatment offers substantial relief in all cases under consideration, actually cures the acquired variety and offers the only rational treatment, if conscientiously pursued, that will make permanently comfortable the congenital variety.

SHORT ABSTRACT OF TWELVE CASES

I realize that claims of conclusive importance cannot be deducted from twelve cases with so little time elapsing since operation. The results have been so prompt in all cases, however, that they seem well worth recording.

Case 1.—Mrs. K., St. Luke's Hospital, Aug. 23, 1910. Appendix removed seven years previously. General visceral ptosis; appendix region free; cemum prolapsed. Taut pull in terminal ileum; apex of kink rolled on itself and lumen obstructed. Terminal arm adherent to cecum and to the descending arm of its proximal portion (Fig. 10, A). Not treated by present line of treatment. Partially relapsed and then placed on postural, support and feeding treatment. Gradually improving but may require another operation to overcome relapsed kink.

Case 2.—Mrs. S., St. Luke's Hospital, Aug. 13, 1910. Chronic appendicitis accompanied by stomach crises with vomiting; extremely anemic. Rest in horizontal position gave relief. Operation showed appendix adherent beneath prolapsed cecum, a distinct pull on terminal ileum with contracted bowel, and distinct kink at mesenteric pull. Terminal portion adherent to cecum and proximal arm prolapsed in pelvis and adherent to broad ligament (Fig. 10 B). After operation, patient was systematically treated by postural, support and feeding treatment. Gained 15 pounds of flesh and her symptoms have disappeared.

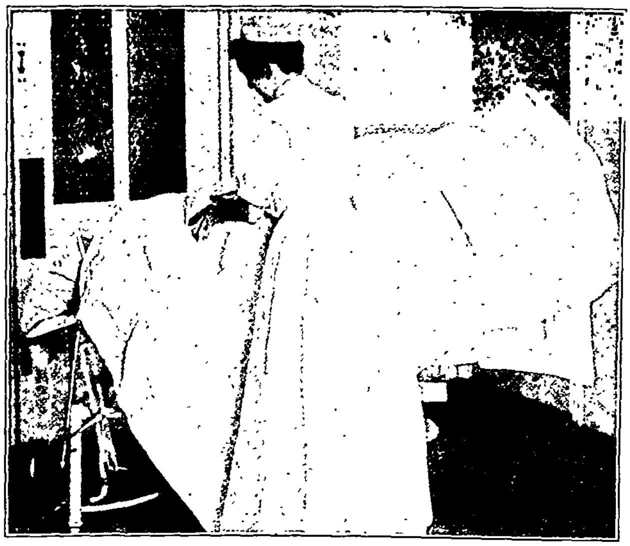

Fig. 8.—Illustrates massage of abdominal muscles with patient in Trendelenburg position. Hospital treatment.

Case 3.—Mrs. M., St. Luke's Hospital, Sept. 16, 1910. General loss of flesh, following childbirth, with laceration of perineum and uterine prolapse. Pain in right side; occasional attacks of vomiting with extreme prostration. Laparotomy showed cecum prolapsed and partially rotated toward umbilicus. Ileum kinked (Fig. 10, C and D) and its arms adherent; appendix free but stiff and injected. Appendix removed, kink relieved and postural, support and feeding treatment instituted. Patient completely relieved and has regained normal flesh.

Case 4.—Miss A. K., St. Luke's Hospital, Sept. 7, 1910. Distinctly so-called "neurotic type" with general visceral prolapse. Retroversion and prolapse of uterus with pelvic symptoms. Pain in right side with periodic attacks of stomach trouble manifested by nausea, anorexia and gas distention. Operation revealed head of colon covered with a peritoneal membrane (Jackson), and double kink of ileum (Fig. 10, F).

lished; (e) with convalescence from operation, a careful *application of a permanent abdominal support or corset* to be worn during the day, always applied with patient in steep Trendelenburg; (f) systematic gymnastics of the abdominal wall for fifteen minutes twice a day, night and morning, with patient in Trendelenburg position without the abdominal support; (g) systematic regulation of the diet after convalescence, with the object of increasing flesh and depositing in all portions of the individual a padding of normal fat.

In the operation, careful observance should be made to ascertain, when a prolapsed cecum is one of the etiologic factors of the bend, if the prolapse is due to a lack of normal blending of the ascending colon with the posterior parietes. If the blending has failed to occur, the defect may be remedied by attaching the outer border of the ascending colon to the peritoneum of the parietes, thus imitating Nature's way of obliterating the mesentery in embryo. F. Gregory Connell[1] utilizes a portion of the Jackson membrane (this membrane frequently being present where the ascending colon has failed to attach) as a means of suspending the head of the large bowel, by including a twisted portion of the upper end of the membrane which has been detached, in the muscles of the abdominal wall in closing the parietal wound (Fig. 5, B and C).

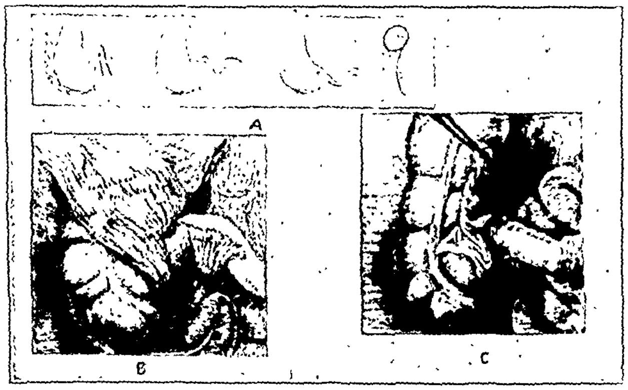

Fig. 5.—(A) Types of Lane kink, from Lane's article. (B) A kink of the terminal ileum covered with a Jackson membrane (one of Connell's cases). (C) Method of utilizing the Jackson membrane in fixing the cecum at its normal level. (Same case from F. Gregory Connell.)

In a large percentage of the cases in which peritoneal blendings have failed to develop, however, there is such a universal visceral prolapse that it is futile to attempt to cure them by any form of "pexies," and I therefore carefully replace the organs, the force of gravity in the Trendelenburg position aiding, and depend on the week in bed with the lowered head and closely fitting bandage to retain the viscera at their normal level until convalescence begins.

Then comes the "tug of war" in the management of these cases. The perpendicular position of the patient with the resumption of routine duties will immediately, without the most strenuous efforts to counteract the effect, precipitate a relapse of the condition of kink with its attending disasters of local distress, stasis, toxemia and obscure anemias, by bringing into play the very factors that caused the difficulty originally.

The patient is fitted with a stout linen bandage constructed in such a manner that it definitely and adequately supports and uplifts the contents of the lower abdomen. These supports can be made after some general pattern (Figs. 6 and 7A), but each one must be carefully fitted by an expert bandage-maker and the surgeon must know that they accomplish the work for which they are intended. The support must be constructed, too, in such permanent shape that its reliability can be depended on. This bandage in women can be replaced later by a properly constructed corset (Fig. 7B).

With this abdominal bandage, the patient may be allowed to assume the perpendicular position and to walk.

Each night before retiring, the patient assumes a position on a Trendelenburg table, improvised or otherwise, with a 15° to 20° inclination and the bandage is removed for the night. After its removal the abdominal muscles should be exercised for fifteen minutes. In a sanitarium or hospital (Fig. 8), this can be superintended by an attendant. At home it can be done by a member of the family. In some cases, if the patient is sufficiently impressed with the necessity for thoroughness, he or she can be trusted to carry out the treatment. The object to be accomplished is the voluntary exercise of the muscles by contracting them against an applied resistance. This resistance can be applied by the hands of the masseur, the patient's own hands or some mechanical apparatus, such as a vibrator or a large wooden ball which can be moved about over the abdomen by the patient. Each portion of the abdomen should be systematically covered and all the muscles made to contract against the applied resistance. An inexpensive home treatment is the tossing or elevating of the ball by successively contracting different portions of the lower abdomen as the ball is moved from place to place.

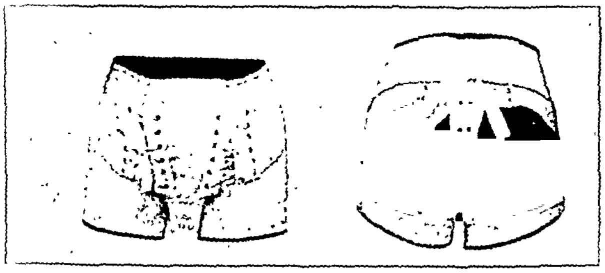

Fig. 6.—Types of bandages employed suitable to both men and women.

The patient then retires after the fifteen-minute exercise of the abdominal muscles combined with the postural treatment. On rising in the morning, before the bath, the same posture is assumed and the exercise repeated. Then after the bath, with the patient still in Trendelenburg position, the abdominal support is applied for the day.

Systematic feeding with the object in view of increasing the flesh, especially the normal deposit of fat of the patient, should be our principal aim in the treatment of these individuals. As a rule this is not a difficult matter after the partial obstruction of the intestines has been removed by the liberation of bands of adhesions and kinks of the intestine which have given rise to the intestinal stasis. Very often a normal, well-selected diet of nourishing food will be readily assimilated and this can be supplemented by cream and, if the bowels are still inclined to require some additional stimulation, a liberal allowance of pure California olive oil may be added, if it is not objectionable to the taste of the individual, the oil aiding in the increase of fat accumulation and its excess acting as a laxative.

If the patient, with the exercise that should be indulged in, is unable to digest a normal liberal diet at the beginning, a careful regulation of predigested foods should be made or the administration of smaller quantities of undigested staple foods at more frequent intervals. I can conceive how it might occasionally be necessary to pursue the careful diet-regulation of the Weir Mitchell method of forced feeding, although in the class of cases under consideration I have not found it necessary. This treatment offers substantial relief in all cases under consideration, actually cures the acquired variety and offers the only rational treatment, if conscientiously pursued, that will make permanently comfortable the congenital variety.

SHORT ABSTRACT OF TWELVE CASES

I realize that claims of conclusive importance cannot be deducted from twelve cases with so little time elapsing since operation. The results have been so prompt in all cases, however, that they seem well worth recording.

Case 1.—Mrs. K., St. Luke's Hospital, Aug. 23, 1910. Appendix removed seven years previously. General visceral ptosis; appendix region free; cemum prolapsed. Taut pull in terminal ileum; apex of kink rolled on itself and lumen obstructed. Terminal arm adherent to cecum and to the descending arm of its proximal portion (Fig. 10, A). Not treated by present line of treatment. Partially relapsed and then placed on postural, support and feeding treatment. Gradually improving but may require another operation to overcome relapsed kink.

Case 2.—Mrs. S., St. Luke's Hospital, Aug. 13, 1910. Chronic appendicitis accompanied by stomach crises with vomiting; extremely anemic. Rest in horizontal position gave relief. Operation showed appendix adherent beneath prolapsed cecum, a distinct pull on terminal ileum with contracted bowel, and distinct kink at mesenteric pull. Terminal portion adherent to cecum and proximal arm prolapsed in pelvis and adherent to broad ligament (Fig. 10 B). After operation, patient was systematically treated by postural, support and feeding treatment. Gained 15 pounds of flesh and her symptoms have disappeared.

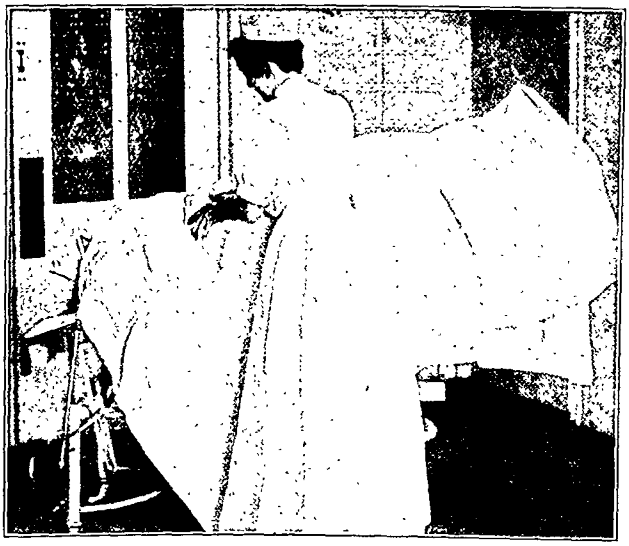

Fig. 8.—Illustrates massage of abdominal muscles with patient in Trendelenburg position. Hospital treatment.

Case 3.—Mrs. M., St. Luke's Hospital, Sept. 16, 1910. General loss of flesh, following childbirth, with laceration of perineum and uterine prolapse. Pain in right side; occasional attacks of vomiting with extreme prostration. Laparotomy showed cecum prolapsed and partially rotated toward umbilicus. Ileum kinked (Fig. 10, C and D) and its arms adherent; appendix free but stiff and injected. Appendix removed, kink relieved and postural, support and feeding treatment instituted. Patient completely relieved and has regained normal flesh.

Case 4.—Miss A. K., St. Luke's Hospital, Sept. 7, 1910. Distinctly so-called "neurotic type" with general visceral prolapse. Retroversion and prolapse of uterus with pelvic symptoms. Pain in right side with periodic attacks of stomach trouble manifested by nausea, anorexia and gas distention. Operation revealed head of colon covered with a peritoneal membrane (Jackson), and double kink of ileum (Fig. 10, F).

Case 5.—Mrs. P. D., St. Luke's Hospital. Indigestion and pain in epigastric and appendicular region; patient suffered with constipation. Operated on once for loose right kidney. General visceral prolapse; neurotic temperament. Liver and all abdominal organs prolapsed and mesenteries long. A distinct Lane kink obstructing the ileum one-third of its caliber. Apex of kink adherent on the broad ligament. Appendix large and patulous (Fig. 10, E).

Case 6.—Mrs. W., Norwegian Tabitha Hospital. Acquired visceral ptosis. Chronic appendicitis with pain in right side, exacerbated when woman was active; symptoms: nausea, indigestion, anorexia and gas distention. Relieved by horizontal position and rest. Loss of flesh and extremely anemic. Operation revealed stiff adherent appendix beneath prolapsed cecum. Terminal ileum kinked and adherent with fine adhesions.

Case 7.—Miss H. M., St. Luke's Hospital. Operated on two years ago for chronic recurrent appendicitis. Patient only had temporary relief while resting during convalescence. The resumption of perpendicular position precipitated old symptoms of pain in right side, attacks of nausea and depression, with loss of flesh, anemia, anorexia, constipation and distention with gas. Always relieved by prolonged rest and bowel regulation.

Diagnosis: Kink of ileum (Fig. 10, G).

Operation revealed well-marked Jackson membrane. Free head of colon but marked kink of terminal ileum with adhesions; general visceral prolapse. Adhesions severed, kink relieved and postural treatment, abdominal support and feeding, with abdominal gymnastics later, completely relieved patient. Gained flesh and all symptoms relieved.

Fig. 9.—An extreme case with visceral prolapse and abdominal protrusion, restored after six months' management. Patient had extreme kink with definite intestinal stasis. Author's case.

Case 8.—Mrs. H., St. Luke's Hospital, Oct. 15, 1910. Chronic pain in right side. Exacerbated at times with nausea, gas distention, anorexia, extreme constipation. Patient lost flesh; extremely anemic. Always improved with prolonged rest in bed. Operation revealed long retrocecal appendix, adherent kink and adhesions of terminal ileum. Ileum rolled in its mesentery and lumen much narrowed. Relief of kink, severing of adhesions with postural, after-treatment, gymnastics and feeding which gave complete relief. (Fig. 10, H.)

Case 9.—Mrs. C., Hinsdale Sanitarium, Dec. 12, 1910. So-called "neurotic type." General visceral prolapse; extreme intestinal stasis. Pain in right side and exacerbation accompanied with extreme stomach pains, nausea, anorexia and most marked anemia. Patient had previously been operated on for cyst of right broad ligament and appendicitis. Operation revealed general visceral prolapse and a mass of adhesions about terminal ileum and cecum. The terminal ileum was looped, the pelvic loop adherent to broad ligament, and through the loop projected an 8-inch loop of distant portion of ileum (Fig. 10, I). All adhesions unraveled and patient treated by postural support, feeding, and later, gymnastics. Patient improved rapidly and promptly. Stasis and pain relieved; digestive disturbances disappeared. Patient gained rapidly in flesh. Two months later, unfortunately, this patient developed a vaginal abscess, which delayed complete recovery, but, notwithstanding, the improvement was remarkable.

Case 10.—Mrs. L. W. I., Hinsdale Sanitarium (aged 42; five children). For five years a sanitarium invalid. Always received benefit from rest, feeding, horizontal position and regulation of bowels. Has had pain in right side with stomach crises, chronic bowel stasis, considerable loss of flesh after each session. Diagnosis: Chronic appendicitis and Lane kink.

Operation showed general visceral prolapse, chronic appendix beneath a prolapsed cecum and well-marked multiple kinks of terminal ileum with adhesions. Patient relieved of kink, appendix removed and adhesions separated. After-treatment instituted, including immediate Trendelenburg, feeding, and, while convalescing and until the present time, postural treatment with abdominal gymnastics. Patient has gained 15 pounds; symptoms completely relieved; toxemia, anemia and stasis disappeared, and patient now is in best of spirits and health (Fig. 10, J).

Case 11.—Mrs. S., St. Luke's Hospital, March 7, 1911. Acquired visceral prolapse. Large woman; one child. Prolapse; retrodeviation. Had appendicitis during previous year. Lost 40 pounds; still weighs 180. Appendix adherent low in pelvis with prolapsed cecum turned to left and adherent to ileum; kink occurring at pull of mesentery. Appendix removed and adhesions separated; ileum replaced and cecum elevated. Uterus suspended on round ligament (Baldy) (Fig. 10, K).

Case 12.—Mr. H. (medical student). Defective type; general visceral prolapse. Had appendix removed five years ago; general adhesions at that time and extensive sepsis following. Since has had intestinal stasis, gradually getting worse. Cathartics of little avail. Considerable anorexia and much gas. Constant pain in right side between umbilicus and McBurney's point; anemia extreme. Diagnosed own case.

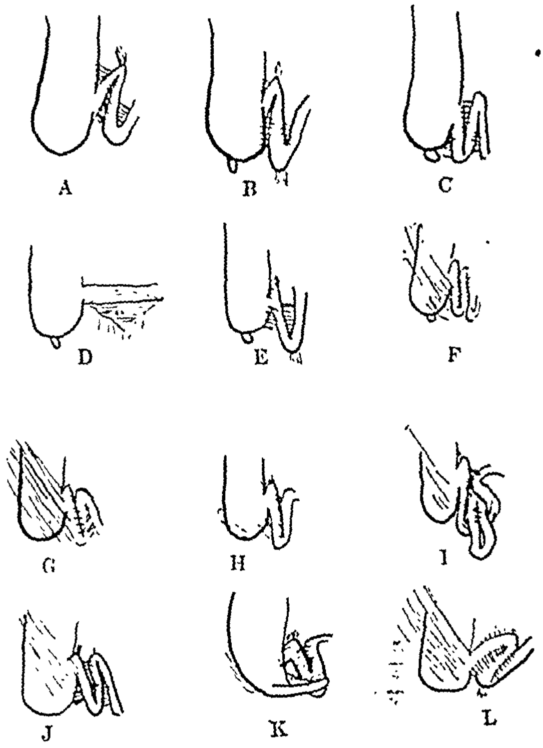

Fig. 10.—Sketches by the author of several of his kink cases.

Operation: Right rectus incision (Fig. 10, L). Cecum low; covered with Jackson membrane but not adherent. Terminal ileum bent acutely 4 inches from its end; apex of bend adherent at bottom of pelvis beneath Poupart's ligament. The two arms of ileum and their two mesenteries firmly adherent for surface of 8 square inches. Adhesions separated and ileum spread out. Patient was treated systematically by posture, bandages and gymnastics in Trendelenburg position. Gained 15 pounds and is now well.

31 North State Street.

ABSTRACT OF DISCUSSION

Dr. W. B. Dorsett, St. Louis: This condition of kinks frequently follows operative procedures. It is not an uncommon thing for the surgeon to say to the patient, "Lie perfectly still." The consequence is that adhesions always occur and frequently produce the condition found in the Lane kink. I have never gone so far as to place my patients in the Trendelenburg position, but have told them that when not in very great pain they may occupy any position in bed except on their "feet or head."

Dr. Arthur E. Hertzler, Kansas City: The pathology of this condition has been described as a "sclerosis mesenterica" by Richter. In the inflammatory condition we have an exudate pushing apart the two layers, including the fibrous tissue of the mesentery. We can predict what will be the subsequent course of an exudate of that kind. When that fibrous tissue develops it contracts. Two years ago I ventured a classification distinguishing between the newly-formed peritoneum, a pseudo-peritoneum and the so-called Jackson membrane, which is nothing more than a dilatation of the subperitoneal vessels. In the first case one may remove one peritoneum and have one left. In the other type, if you remove it, you have no peritoneum left and deprive the organ of its protection.

Dr. Louis J. Hirschman, Detroit: Did I understand Dr. Martin to state that in the treatment of this kink, after breaking up the adhesions, the ileum was stitched to the parietal wall?

Dr. Franklin H. Martin, Chicago: After breaking up the adhesions about the ileum kink if I find that a long mesentery is present on the ascending colon I imitate Nature's way of obliterating the mesentery by stitching the peritoneum of the outer border of the ascending colon to the parietal peritoneum, but I do not attempt to stitch the ileum.

Dr. Louis J. Hirschman, Detroit: In case of prolapsed cecum we have been led to believe that by stitching prolapses of the sigmoid flexure, particularly, and following up the histories of cases in which sigmoidal adhesion to the abdominal wall has been performed for the correction of the prolapse, a kink forms following operation just beyond the point where a fixation was made. We have always believed that in these cases of ptosis with elongated mesentery that it was not imitating Nature to suture that to the peritoneum or abdominal walls, but that we should incise the mesentery in a longitudinal direction and sew it transversely, thereby shortening the mesentery, bringing the viscus back to its proper place and not creating any pelvic or peritoneal adhesions where Nature did not intend them.

Dr. C. E. Barnett, Ft. Wayne, Ind.: The question just now is being somewhat investigated as to the interference with the kidney function of the Trendelenburg posture under anesthesia. I should like to ask Dr. Martin whether he has investigated the quantity of urine passed during this posture? It seems to me that our anesthetic hazard is considerable anyhow and that if the kidney is crippled at all, the Trendelenburg posture afterward would be a hazard that one could not risk. Regarding oils in the peritoneal cavity, I hope that their use does good, yet I have never believed in it. I do believe though that Dr. Martin's method of avoiding adhesions would answer better than any other way.

Dr. Franklin H. Martin, Chicago: In answer to the slightly implied criticism of pexy or fixation of the ascending colon: The large bowel at about the fifth month of embryo life rotates to the right and its whole mesentery becomes attached to the parietes to the right, the posterior layers disappearing after blending with the parietal peritoneum. Now if the cecum or larger bowel has failed to rotate—and it has in many cases—then we are not doing pexy; we are simply imitating Nature's way of obliterating the mesentery. Not only is it theoretically correct, but practically it works.

Honesty, Soul of Research.—The very soul of research, finally, is the highest degree of honesty. The investigator should see clearly and accurately with an eye single to the truth. He has to consider not only the observations which fit his theory, but any others as well. The erratic cases invariably make trouble, but they are often disguised blessings. They may indeed be of far greater moment than those which have been anticipated, for they may point the way to entirely unsuspected facts. After the investigator has completed his examination of a group of questions which have interested him, his leading idea, his tests and his results must be described with scrupulous exactness. In thus reporting his work he should strive to be like clearest crystal, receiving the light and transmitting it, untinged by any trace of color.—Cannon in *Science*.

FINGER PHENOMENON

A NEW DIAGNOSTIC SIGN OF ORGANIC HEMIPLEGIA

(PRELIMINARY REPORT)

ALFRED GORDON, M.D.
PHILADELPHIA

Since Babinski's discovery of his invaluable toe phenomenon as a pathognomonic sign of an organic involvement of the pyramidal tract of the central nervous system, a number of observers have concentrated their attention on various other reflex manifestations. They all, however, have reference to the lower extremities (Oppenheim, Gordon, Shäfer, Mendel-Bechterew, Grasset, Marie, Throckmorton and others). Hoover also described a valuable phenomenon enabling one to distinguish between an organic and functional disability. Here again it is the lower extremity that reveals the differentiating manifestation.

The upper limb has received comparatively little attention in this respect, or speaking more correctly, very few reflex phenomena have been observed and described with reference to the upper limb, which could be considered as indicative of an organic involvement of the cerebrospinal axis. Bechterew's or scapulohumeral reflex and the more recent "inversion of the radius reflex," described by Babinski are practically the only reflex phenomena which, with few exceptions, may be considered of diagnostic value. By no means, however, do the latter possess the clinical importance of the toe phenomenon. The paucity of diagnostic reflex phenomena in the upper limbs is therefore striking.

Although in the majority of cases there are no special difficulties in recognizing an isolated brachial monoplegia of cerebral origin or a paralysis of an arm, accompanying hemiplegia, nevertheless we encounter now and then isolated cases where the diagnosis of a functional and organic paralysis of an upper limb is made with some hesitation, to say the least.

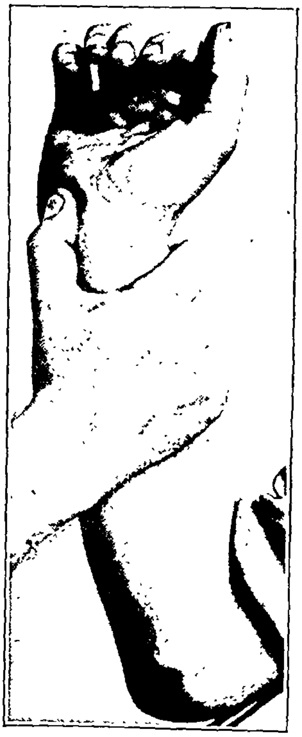

Fig. 1.—Position of thumb on pisiform body before pressure

In a certain small group of cases of hemiplegia dating from infancy, the paralyzed upper and lower limb or one of them (upper) may be free from spasticity and hypertonicity of the muscles, characteristic of ordinary hemiplegia, and present indeed a flaccidity. The latter together with the arrested development of the entire limb (bone as well as muscles), may suggest an old anterior poliomyelitis. In such cases the difficulty of diagnosis may be great, especially when the lower extremity has greatly improved and the upper extremity remained disabled; or when the lower extremity was originally very slightly involved and the largest part of the damage was done to the pyramidal fibers supplying the upper limb (cerebral monoplegia). The need of some diagnostic signs in cases of the category just mentioned is certainly evident. I have observed the following phenomenon in eight cases of complete hemiplegia.

The forearm of the patient's affected limb is elevated and the elbow is placed on a table. The support of the elbow is, however, not essential. The patient's wrist is then lightly embraced by the examiner's hand, with the thumb against the pisiform bone and the other fingers on the dorsal surface of the wrist (Fig. 1). Or one of the examiner's hands may be placed against the back of the patient's wrist, and thumb of the other hand against the pisiform bone. Pressure is then produced with the thumb against the pisiform body and especially on its radial side. Care must be taken not to produce pressure on the dorsal surface of the wrist where the extensor muscles are located. The fingers are then seen to extend and sometimes also to spread in a fan-like form, as Figure 2 illustrates the phenomenon in one of my patients. In some cases the extension is observed only in the last two fingers, in others, all five fingers extend, and in still others, the thumb and the next two fingers. The extension is sometimes more prompt and more distinct when the ring finger is slightly raised before the test and kept raised during the test. This finger must be supported very gently and in a semi-extended position.

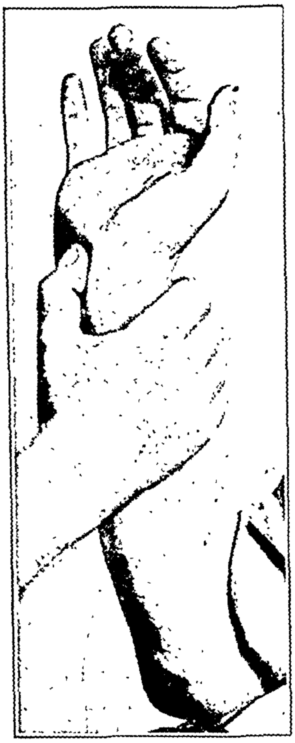

Fig. 2.—Pressure on radial side of pisiform body producing fan-like extension of fingers.

The phenomenon is not very marked in hemiplegias of old standing, in which the contracture of the fingers is very pronounced. In three such cases (not included in the series of eight) I could not obtain this reflex. In six cases of hemiplegia of comparatively recent occurrence, viz.: between two and six months, the reflex was prompt and was obtained at the first attempt. In the remaining two cases the phenomenon was elicited only after two or three tests made in succession. The eight cases examined were present in three children aged between 2 and 13 years, and in five adults. For the purpose of control I examined fifteen normal individuals, four cases of bracial palsy of poliomyelitic origin, and three cases of hysteric hemiplegia. The latter were very striking cases, all occurring after traumatic shocks; the palsy of both arm and leg was complete and rigidity was present. Hemianesthesia of functional type was conspicuous. Although the tendon-reflexes were all increased, Babinski's toe phenomenon was absent. The phenomenon of the fingers described here was absent in every one of them.

The eight hemiplegics, in whom the finger phenomenon was invariably present, do not constitute, of course, a sufficiently large number for generalization. Nevertheless, the continuous presence of the finger phenomenon in them and the absence of the latter in functional cases as well as in fifteen normal individuals warrant me in bringing the phenomenon to the attention of the profession. Further observation on a large number of cases is necessary.

As to the physiology of the reflex, it is well to remember that two muscles are attached to the pisiform bone, viz., flexor carpi ulnaris and abductor minimi digiti. That pressure on the insertions of these muscles should produce an elevation of all the fingers or only of the last two, or of the first three, is certainly an unexpected manifestation. In normal individuals an identical pressure on the pisiform bone (especially on its radial side) produces either no response at all or else a flexion of all the fingers.

An analogy between the finger phenomenon and phenomena observed in the lower extremity is striking. Normally, irritation of the plantar surface causes a flexion of the toes. When the pyramidal tract is involved, extension of the toes will be observed by the same test (Babinski). Normally pressure on the flexor muscles of the leg produces either no response or flexion of the toes. When the pyramidal tract is involved, extension of the toes will follow on the same test (A. Gordon). An identical condition is observed in the mechanism of the finger phenomenon described here: instead of flexion we obtain extension. Similar to the toe phenomenon, the finger phenomenon also strongly indicates an involvement of the pyramidal tract, as apparently it coincides with all other symptoms of a palsy of cerebral origin.

Whether the "finger phenomenon" is constant in hemiplegia, I am unable so far to say, as I have not examined a sufficiently large number of cases. If this phenomenon can be confirmed on a very large number of cases, its importance becomes obvious.

A CASE OF SPORADIC ELEPHANTIASIS

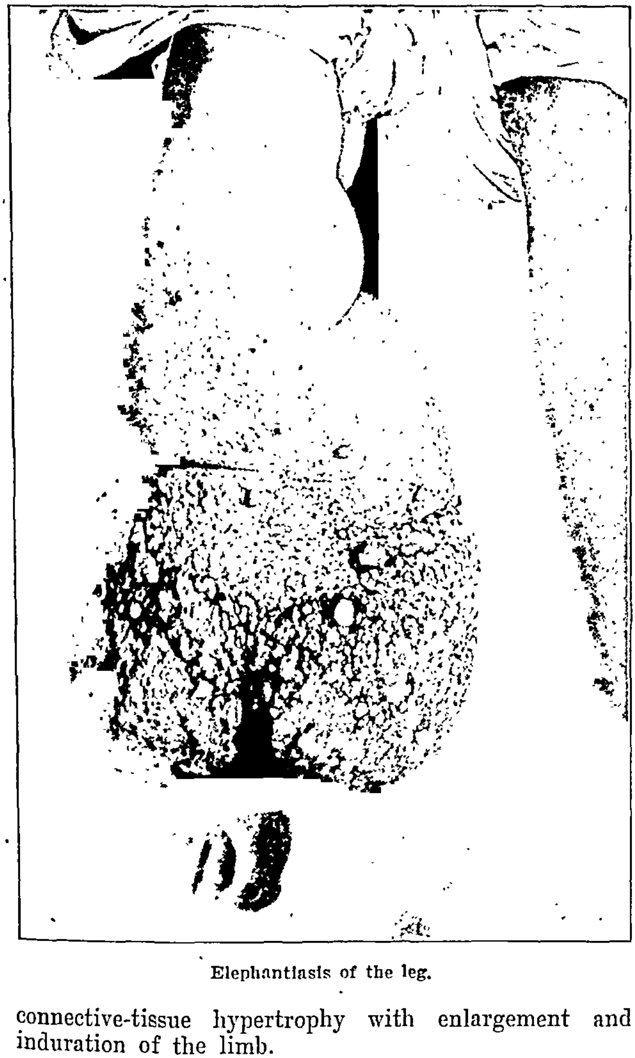
GILMAN J. WINTHROP, M.D.
MOBILE, ALA.

The case reported below is of interest chiefly because of puerperal thrombophlebitis as an etiologic factor.

History.—Mrs. N., white, aged 48, widow, native and resident of Alabama. No family history of tuberculosis, neoplasm or elephantiasis. Patient had measles, pertussis and varicella as a child. At age of 15, she had a mild attack of erysipelas of the left leg, which lasted a week or ten days and gave no further trouble. Menstruation began at age of 15 and has always been normal. She is the mother of five children, the oldest now 25 and youngest 15 years of age. A healthy, active woman until onset of present condition. Following the birth of her second child, twenty years ago, she developed "childbed" fever and a few days later a "milk leg" of the right limb. A painful, red swelling appeared in the right groin and the right ankle became somewhat swollen and edematous but showed no signs of local inflammation. The swelling about the ankle gradually extended to above the middle of the leg but disappeared, in great part, when the patient remained in bed or kept the leg elevated. Occasionally she suffered intense pain in the leg, usually accompanied by an erysipelatous-like inflammation with chills and fever. The skin exuded a milk-like fluid, which was especially profuse if the skin was bruised or broken, as not infrequently occurred. About ten years ago she noted that the leg was becoming gradually harder and the skin thicker and nodulated. The swelling no longer decreased when she was in bed or elevated the limb. This hardening of the tissues and thickening of the skin has slowly increased and extended toward the knee.

Examination.—The patient is poorly nourished; thoracic and abdominal organs are apparently normal. The right leg below the knee is enlarged, firm and indurated. The skin is thickened and nodulated, especially on the posterior surface of the limb. The sole and dorsum of the foot are not involved, but behind, the hypertrophy begins at the heel and merges into the growth above. Between the folds of hypertrophied skin the surface is foul from moisture and exfoliated epithelium. An eroded area on the inner and posterior part of the growth exudes a serous fluid. The blood shows no filaria after repeated examinations, and the cellular elements and hemoglobin are about normal. The urine is normal.

It would seem that the thrombophlebitis following labor produced chronic edema of the leg or by its extension caused an obliterative inflammation of the lymph-channels about the vein, with resulting lymph stasis. The persistent lymphedema produced a gradual connective-tissue hypertrophy with enlargement and induration of the limb.



Elephantiasis of the leg.

The nodular hypertrophy of the skin and subcutaneous areolar tissue is well shown in the photograph.

204 Conti Street.

For Untrammeled Health Officials.—Mrs. Caroline Bartlett Crane, speaking before the Illinois Woman's Press Association on "Common Problems of American Cities," emphasized particularly the need of an untrammeled health department in every city, with a well-paid health officer who could not be deposed or his work rendered useless by the will of some political boss. Mrs. Crane urged all members of the association to interview personally any health officer accused of inefficiency and ascertain if he were hampered in his work, if he had proper facilities for performing his duties and a sufficient number of assistants.

THE USE OF REBREATHING IN THE ADMINISTRATION OF ANESTHETICS [*]

W. D. GATCH, M.D.
BALTIMORE

Since the very introduction of ether and chloroform the use of rebreathing in administering them has been under discussion. With chloroform it has seldom been permitted, while with ether until recent years it was considered desirable,[1] and ether was given almost exclusively by means of a closed inhaler of some sort. Since the introduction of the open method of etherization, however, rebreathing has fallen into disfavor, and writers now pretty generally condemn it.[2] It is my purpose to show that, contrary to this common opinion, rebreathing when properly regulated and when the oxygen supply is ample is harmless and can be put to a valuable use. The evidence in favor of this is derived partly from a series of 2,500 gas-oxygen and gas-oxygen-ether anesthesias given by a closed method at Professor Halsted's clinic, and partly from the recent and very important work of

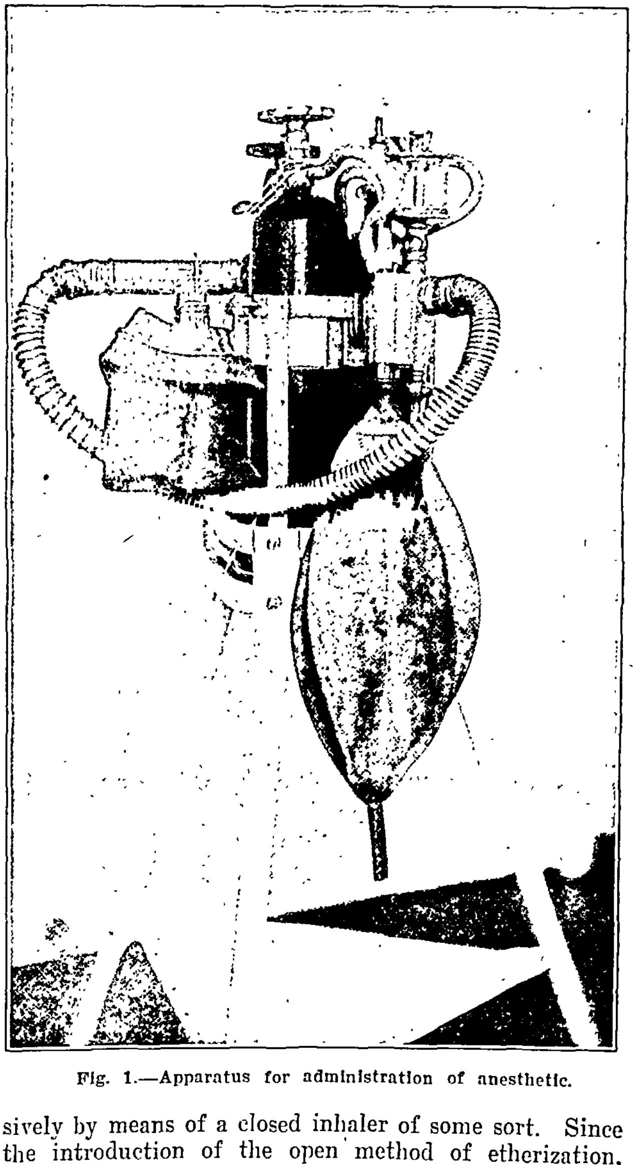


Fig. 1.—Apparatus for administration of anesthetic.

---

[*] Read in the Section on Pathology and Physiology of the American Medical Association, at the Sixty-Second Annual Session, held at Los Angeles, June, 1911.

the physiologists — Henderson,[3] Hill,[4] Haldane[5] and others — on the carbon-dioxid metabolism of the body. In a preceding paper[6] I have discussed the use of rebreathing in giving nitrous oxid with oxygen; here I wish to consider its use in administering any inhalation anesthetic, and more especially ether.

The subject can be approached most simply by considering the harmful results supposed to follow the administration of ether by the use of closed masks. I shall speak only of ether for the present, because most of the investigations bearing on the question of rebreathing have had to deal with this anesthetic. The ill effects in question may be grouped under two heads:

1. Injury to the lungs.
2. General toxic effects.

Dreser,[7] Offergeld,[8] Poppert[9] and Hölscher[10] have studied very carefully the effects of ether vapor on the respiratory passages. Dreser regards any concentration of vapor which cannot be inhaled by the patient while in the conscious state without discomfort and coughing as harmful to the lungs. Applying this test, he fixed on 6 per cent. to 7 per cent. as the highest concentration which should be used. Offergeld, experimenting on animals, found that the lungs after etherization by a closed method showed much graver injuries than after etherization by an open method. With the closed method he found extensive fatty degeneration and desquamation of the epithelium of the air-passages, also many minute hemorrhages into the alveoli; many of the animals died of bronchopneumonia. With the open method the pulmonary lesions were of a comparatively unimportant character, unless the administration was frequently repeated at short intervals. Poppert, whose experiments were similar to Offergeld's, concluded that ether vapor is more irritating to the lungs the greater its concentration. Hölscher studied the distribution of secretion in the air-passages during ether narcosis. He found that there is only a very slight secretion from the epithelium situated below the level of the larynx. By putting coloring materials into the mouths of anesthetized animals he proved that mucus and saliva may be aspirated into the deepest air-passages. His conclusion was that "affections of the air-passages occurring after ether are for the most part due to the aspiration of infectious mouth contents."

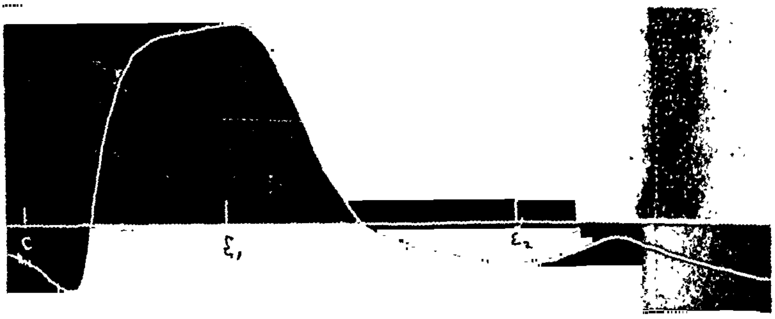

Fig. 2.—Tracing obtained from the pyloric ring of a frog suspended in a moist chamber into which ether vapor and carbon dioxid could be passed. At C. carbon dioxid was passed over the muscle, causing a sharp contraction. At E_1 very dilute ether vapor was turned on with the carbon dioxid, causing immediate relaxation. At E_2 the ether was turned off.

We can summarize the experimental results dealing with the effects of ether vapor on the lungs as follows:

1. The irritant action of the vapor varies according to its concentration.
2. Postoperative lung complications are frequently caused by the aspiration of mouth contents.
3. The greater severity of the pulmonary lesions found after experimental etherizations by the closed method can be satisfactorily accounted for by the great concentration of ether vapor in the closed masks and the greater liability to aspirate mouth contents when these are used.

We now have to consider why the general toxic effects which follow ether anesthesia are more severe after the closed method than after the open method. Writers are almost unanimous in asserting that they are so. The work of Ladd and Osgood[11] is very important in this connection. These authors studied the frequency of postanesthetic vomiting in patients after etherization with the Blake cone and in those etherized by the "gauze ether" method. Vomiting was much more frequent and severe among the former patients than among the latter. With the Blake cone cases they found acetone in the urine after operation in 88 per cent. of the cases, while with the "gauze ether" cases they found it in only 26 per cent. The technic and advantages of the open method are discussed by Miss Magaw,[12] who reports 14,000 cases with most satisfactory results. In short, there is no doubt that this method of etherization is better than the rather crude closed methods it has replaced. Of its disadvantages and dangers I shall speak later.

To what causes are the ill effects which follow the closed method to be traced? The causes commonly held responsible are the following[2]: (1) anoxemia, (2) over-concentration of ether vapor, (3) toxic organic substances in the expired air, and (4) excess of carbon dioxid in the expired air. The first and second of these possible causes are, I believe, the real ones. The third is imaginary, since the physiologists have demonstrated beyond any reasonable doubt that there are no organic poisons in the breath.[13] Concerning the excess of carbon dioxid, it is the purpose of this paper to show that it is harmless, and can be put to a valuable use.

It is perfectly evident that anoxemia and overdosage of ether, evils almost unavoidable when this anesthetic is given in a tightly closed mask, must do harm. We know that a deficiency of oxygen will quickly cause the gravest injuries to the tissues. Dreser found that the gas within closed etherizing masks would at times put out a burning candle! He also found that the ether vapor within the closed masks sometimes reached a concentration as high as 34 per cent., while 6 to 7 per cent. is the greatest concentration which can be inhaled without irritation to the air-passages. With such an overdosage of ether as this it is true that the excess of carbon dioxid within the closed masks is injurious, for it stimulates powerfully the respiration and leads quickly to an overabsorption of ether by the blood.

If the truth of what has just been stated be admitted, it follows that if we can prevent anoxemia, overconcentration of vapor, and too great a depth of anesthesia, we can obviate most of the serious objections to the closed method of giving ether.

I have so far limited the discussion to the administration of ether, but it will apply, in part at least, to all anesthetics given by inhalation—to chloroform, ethyl chlorid and nitrous oxid. With all of these it is evident that anoxemia must be prevented. With chloroform and ethyl chlorid, on account of their great toxicity, overdosage is the most important problem in administration. With nitrous oxid, in the absence of asphyxia overdosage is impossible. Ether requires a special consideration on account of the peculiar irritant action of high percentages of its vapor on the lungs and air-passages.

I have made use of the principles laid down in the foregoing paragraphs in developing a method of anesthesia, the technic and advantages of which I now wish to describe. Nitrous oxid and, if necessary, ether are the anesthetics used. The apparatus employed[14] consists essentially of a mask connected by a piece of flexible tubing to a rubber bag. This forms a closed space into which the patient breathes. On the mask is a valve-box by means of which the patient can be made to breathe to and fro into the bag, or to inspire from the bag and expire into the air, thus emptying the latter. The bag is attached to a small box, through which the current of gas must pass back and forth from the bag to mask. Into this box nitrous oxid and oxygen are admitted, and ether, drop by drop, from a receptacle above. The ether is vaporized in the box from a series of drip plates, and any excess of ether can be drained off at once by a stopcock. The method of administration is simple. The mask is adjusted carefully to the patient's face and the bag filled with nitrous oxid containing a very small amount of oxygen. The patient is made to breathe this mixture in and out through valves, thus replacing all the air in his lungs with nitrous oxid and oxygen. The bag is next refilled with the same mixture of gases which the patient is now made to rebreathe for from five to eight minutes. At the end of this time he is allowed to empty the bag, breath by breath, into the air, after which it is refilled, and the same procedure is repeated. Oxygen is given, without any attempt to estimate its exact percentage to the nitrous oxid, in quantities just sufficient to keep the patient's color free from cyanosis. If desired, nitrous oxid can easily be given under positive pressure, by keeping the bag slightly overdistended. This is sometimes a useful procedure in managing difficult cases. Anesthesia is usually established in less than two minutes. If the anesthesia is unsatisfactory with nitrous oxid alone, ether is added. This combined nitrous oxid-ether anesthesia has many points of practical and scientific interest and calls for a special consideration.

Ether is not given till the patient's respiration has been stimulated by the accumulation of carbon dioxid which results from the rebreathing. It is then added drop by drop. The heated gases quickly evaporate it from the drip plates, and it is rapidly absorbed by the blood because of the increased pulmonary ventilation. The most difficult subjects can thus be deeply anesthetized.

I have already referred to Dreser's experiments in which he proved that from 6 to 7 per cent. of ether vapor is the greatest concentration which can be inhaled by a patient in the conscious state without irritation and coughing. Precautions must be taken to keep the concentration of ether vapor in the mixture of gases below this level if we wish to do away with any possibility of injuring the lungs. This is quite easily accomplished, as the following simple calculation will show. The gasbag moderately distended holds about 10 liters of gas, the mask and tubing hold about 1 liter, and the entire respiratory system of the patient holds about 3 liters. When the patient is rebreathing, these all form one closed space with a total capacity of about 15 liters. Our problem is this: How much ether must be added to 15 liters of gas to make the concentration of ether vapor 7 per cent.? Professor Abel has very kindly performed this calculation for me and gives the amount of ether as 4.2 c.c. He desires me to state, however, that the conditions of the problem are so variable that the amount of ether required cannot be determined with absolute accuracy. The varying temperature in the apparatus, the loss of ether through leaks and by absorption in the lungs are factors for which no accurate data can be furnished. But absolute accuracy is not necessary, because the constant loss of ether gives us a wide margin of safety so that we can probably add ether much faster than our calculation allows without exceeding the danger limit.

With the drops of ether falling at the rate of 120 to the minute I have found that it takes two and one-quarter minutes to add the 4.2 c.c. Therefore, if we give ether at this rate and take precautions not to keep it dropping for more than two minutes at any one time, and to keep the bag constantly full of gas, we can be sure that the ether vapor will not reach a concentration greater than 7 per cent. If the anesthetist does not care to follow some such rule as this he can easily, and I think with perfect safety to his patient, estimate the strength of ether vapor by its odor as it escapes from the valve-box. In fact, ether is usually given for so short a time that even if it were administered in a somewhat concentrated form it would probably do no harm.

It has been found unnecessary to give ether constantly during the administration. When enough has been given to produce satisfactory anesthesia, this can be maintained with nitrous oxid alone, even in cases requiring a deep narcosis. This is to be explained by the fact that the rebreathing prevents the ether, once dissolved by the blood, from being thrown off as rapidly as it would otherwise be by the lungs, which are the organs by which it is practically all eliminated.[15] Suppose, for example, that a patient having a certain amount of ether dissolved in his blood is given some fresh nitrous oxid and oxygen to rebreathe. The ether will be thrown off from his lungs till the tension of its vapor in the gases being breathed will equal that in the blood. When this occurs no more ether will be eliminated until a new supply of gas is furnished.

---

[14] I have already described the apparatus elsewhere in some detail (Note 6). It will be noted that the arrangement for giving ether has been changed so as to permit of a more accurate dosage. The method of administration is practically unchanged, except that I now allow rebreathing for somewhat longer intervals

[15] Hewitt: Anesthetics and Their Administration, Ed. 3, p. 50; Cushny: Pharmacology and Therapeutics, Ed. 4, p. 166; Cushny: The Exhalation of Drugs by the Lungs, Jour. Physiol., xl, 17; Nicloux: Elimination de l'éther contenu dans le sang après l'anesthésie pendant la *période de retour*, Cont. rend. Soc. biol., 1907, i, 8.

Not only can we prevent the elimination of ether by rebreathing, but we can also hasten the elimination by a rapid ventilation of the lungs with fresh gas. During the process of rebreathing, carbon dioxid accumulates in the body and stimulates the respiratory center so that the breathing becomes deep and rapid — often fifty or sixty respirations to the minute. When a patient, anesthetized in the way I have described and breathing at such a rate, is given a fresh supply of gas and allowed to discharge each breath into the air, he apparently rapidly rids himself of the small dose of ether he has been given. Thus it is possible to anesthetize a patient so deeply that he will not stir during a Whitehead operation, and yet have him conscious before leaving the operating room. By careful administration we can in most cases keep the patient from knowing that he has been given any ether at all, so complete and rapid is its elimination.

I would suggest that this method of removing a volatile anesthetic by rapid ventilation of the lungs be used at the close of every administration of chloroform or ether. The increased pulmonary ventilation can be easily brought about by making the patient breathe in and out, through valves, air or oxygen containing a small percentage of carbon dioxid. I have had such a mixture of oxygen and carbon dioxid prepared which contains 7 per cent. carbon dioxid, but have not had the opportunity to give it a clinical trial.

In this connection it is interesting to consider the effect which morphin has on the elimination of ether or chloroform from the body. Morphin decreases markedly the rate of pulmonary ventilation.[16] Large doses of it must therefore retard the elimination of the anesthetic and thus increase its toxic action. It is often possible to detect the odor of ether or chloroform on the patient's breath for several hours after operation. This slow excretion may be due, in part at least, to the morphin, a hypodermic of which is necessary before or after almost every anesthesia. Perhaps this effect of morphin can be prevented by means of the method I have just described for quickly eliminating the anesthetic.

In the preceding paragraphs I have discussed how ether can be safely introduced and speedily removed from the patient's system. During its stay therein we are powerless to prevent its toxic action. By giving it, however, in combination with nitrous oxid and morphin we can reduce its dose, and therefore its ill effects, to the minimum, since the major portion of the anesthesia is produced by the other two drugs. It is probable also that the effect of ether when thus administered with other narcotics is relatively much greater than when given alone, as it is well known that narcotic drugs given in combination reinforce one another's action.[17] Thus the powerful joint effect of morphin and scopolamin has been explained.

I shall devote the remainder of this paper to matters of direct clinical interest. The form of anesthesia herein described has now been in use in the surgical clinic of the Johns Hopkins Hospital for two years. Here over 2,500 patients have been anesthetized by this method. It is now our routine form of anesthesia for all operations except those on the face, upper air-passages or cranium. In these we have found it inconvenient on account of the difficulty of keeping the mask in place.

Before operation the patient is given an enema and deprived of food for several hours, but is allowed to take small quantities of water. About thirty minutes before the anesthesia is begun he is given a hypodermic of morphin and atropin, the dose for an adult being morphin one-sixth grain, atropin 0.01 grain. The anesthesia is started after the patient has been placed on the table and while the field of operation is being surrounded by sterile towels. It is established so quickly that the incision can usually be made in two minutes after the mask has been put on. Any depth of anesthesia which the condition of the patient and the nature of the operation may require can be easily obtained, because of the control of the patient's respiration which is given by the rebreathing. In abdominal operations, if the increased activity of the respiration is inconvenient, it can be prevented by giving a fresh supply of gas at frequent intervals. The bleeding during gas-oxygen or gas-ether anesthesia is about the same as during open ether anesthesia. The patient's temperature, provided he is kept dry and covered, will be found elevated from 0.5° to 2° after an hour's operation. With light narcosis under nitrous oxid and oxygen alone, the pulse may be rapid (from 140 to 160 to the minute) but this is of no significance provided it is regular and of good quality, and there is no hemorrhage. The rapid heart-rate decreases when ether is given.

This form of anesthesia is especially well suited for long operations. In fact the anesthesia does the patient so little harm that within reasonable limits the duration of the narcosis need not be considered. The surgeon can therefore operate with a deliberation and attention to detail that would otherwise be unjustifiable. The following typical cases show the truth of this contention:

Case 1.—The patient was a negro man, aged 27, in good physical condition. Operation: Excision of a sarcoma from the right popliteal space, and blood-vessel transplantation. Duration of anesthesia, five hours. The pulse-rate per minute varied from 72 to 100. The blood-pressure at the end of four hours of anesthesia was 130 mm. of mercury. The patient regained consciousness before leaving the table. He had no headache, nausea or vomiting, though he was given water at once. His urine after operation contained no albumin or acetone. He was allowed to rebreathe at two and one-half and three-minute intervals. The narcosis was deep and quiet. Ether was given with the gas for the first half hour.

Case 2.—The patient was a white woman, aged 30, in rather poor condition. Operation: Resection of the ascending and transverse colon. Duration of anesthesia two hours and five minutes. No ether was used. The narcosis was light, the patient at times moving her limbs. Recovery was immediate and unattended with headache or vomiting.

Case 3.—The patient was a colored woman, aged 30, in good condition. Operation: Excision of the right breast, pectoral muscles and axillary glands for advanced cancer of the breast, Thiersch skin grafting of the raw surface of the breast. Duration of anesthesia, three hours and fifty-five minutes; 2½ ounces of ether, 130 gallons of gas and 30 of oxygen were used. The anesthesia was quiet and satisfactory, the recovery immediate and without headache, nausea or vomiting.

I could report many more cases similar to the above, but these show sufficiently well how little the patient is injured by this form of anesthesia. A word of caution is, however, necessary. This is that during any administration, and especially during a long administration, the patient's breathing must be kept free and unobstructed, and his color good. If a patient has to work hard for every breath he soon wears himself out. The color of the blood in the wound, the hue of the patient's face, and the character of his breathing as shown by the movements of the rubber bag are the best indicators of his condition. The surgeon himself can hardly fail to notice these. If the patient's breathing cannot be kept unobstructed the use of the apparatus should be abandoned at once and some other method of anesthesia used.

---

[17] Führer: [illegible] Untersuchungen über die Mischnarkose, Münc[illegible] 1911, No. 4; Bürge: Die Wirkung von [illegible] Deutsch. med. Wchnschr., 1910, Nos. 1 a[illegible]

We have had three fatalities, during or immediately after operation, in our series of 2,500 cases. How much the anesthesia was to blame for these may be judged from the following reports:

FATALITY 1.—The patient was a colored woman, aged 44, with exophthalmic goiter of four years' standing. She had an irregular, intermittent pulse, the rate of which had been between 120 and 140. Her heart was enlarged, and she had ascites and edema of the ankles. During the last week of her life she had several severe attacks of dyspnea, associated with extreme rapidity and irregularity of the pulse. For these she was given a course of digitalis, which improved her condition so much that it was thought she could withstand a partial thyroidectomy. When the mask was placed over her face, she made a very slight struggle and took several shallow breaths. The operator then saw the superficial veins of her neck suddenly dilate. This apparently marked the time of death, and occurred within half a minute of the time the anesthetic was started.

FATALITY 2.—The patient was a man with aortic and mitral insufficiency, on whom it was proposed to do a perineal prostatectomy. He was given ether with the gas and oxygen. The anesthesia went very well till the patient was placed on the perineal table with his buttocks elevated; then he became cyanotic and died. An immediate autopsy revealed the presence of a large pericardial effusion, the presence of which had not been recognized before operation.

FATALITY 3.—The patient was a girl of 16, with multiple infectious arthritis; general condition poor. Operation: Injection of both knees with oil and manipulation of knees, ankles and elbows. Duration of anesthesia fifteen minutes. The anesthesia was uneventful, except for a marked increase in pulse-rate while each joint was being manipulated. At no time was the breathing obstructed. At the close the pulse-rate went up very rapidly; the color became cyanotic and could not be cleared up with oxygen. The breathing became weaker and weaker and finally ceased.

An autopsy showed a very large thymus and hypertrophy of all the lymphatic tissues. The pathologists gave status lymphaticus as the cause of death.

The first and second of these patients had circulatory disease of such gravity that the anesthesia is not to be seriously blamed for the deaths. How the third fatality was brought about I am at a loss to understand. The toxicity of nitrous oxid is certainly too low to have caused it.

Notwithstanding these fatalities I believe that this form of anesthesia properly employed is well suited for cardiac cases. Two cases of cesarean section performed by Prof. J. W. Williams on women with serious valvular lesions will show the grounds for this belief. Both women were in about the seventh month of pregnancy, and in both delivery was necessary to save the life of the patient. One of the two was *in extremis* and her death on the table was regarded by the operator as probable. Both women had such urgent dyspnea that the anesthetic had to be started with the patient sitting upright. The same method of administration was employed in both cases. Each patient was given a hypodermic of morphin large enough to quiet her. In inducing anesthesia great care was exercised to avoid the least excitement or struggling on the part of the patient. Both were allowed to rebreathe oxygen till the respiration was stimulated before any nitrous oxid was given. Enough ether was used to give a quiet anesthesia. The operations were performed with the patients' bodies elevated at an angle of 20° to 30°. The pulse of both patients was much better during anesthesia than before, and the operator was able to proceed without undue haste. Both patients made an excellent recovery.

I have hitherto spoken of the advantages of an excess of carbon dioxid in the blood — a hypercapnia — during anesthesia. Our clinical experience has certainly shown that this, to the degree we permit, is harmless. Hill and Flack[4] state that "the effects of carbon dioxid on the heart can always be quickly recovered from, even if the blood-pressure has sunk to zero." These authors found that carbon dioxid up to a percentage of 35 in the air breathed stimulates the respiration, while above 35 it depresses it; also that percentages up to 22 produce a rise in blood-pressure, while higher percentages cause a fall. Of course it is impracticable to determine exactly what percentage of carbon dioxid a patient is breathing. The anesthetizer must regulate the time of rebreathing so that the patient's respiration is moderately stimulated. The periods of rebreathing for 10 liters of gas range from three to five minutes, any leakage from the apparatus being meanwhile made good by the addition of fresh gas.[18]

Does a deficiency of carbon dioxid in the blood —acapnia —do serious harm? The work of Henderson[3] on this problem is so well known as to require no more than a reference here. He has been able to reduce animals to a state of extreme shock by overventilation of their lungs. He asserts that acapnia causes complex osmotic changes in the tissues, which result in a passage of water from the blood into the lymph and into the tissue-cells and a dilatation of the finer veins. Interference with the normal filling of the right side of the heart by this process is the essential phenomenon in surgical shock. In extreme cases of acapnia the blood-stream is so scant and the respiration so feeble that the tissues do not receive the necessary amount of oxygen. An asphyxial acidosis results which does the body-cells irreparable injury. Whether we accept Henderson's theory or not we must admit that the accumulation of carbon dioxid by the process of rebreathing is an efficient stimulus to the respiration and circulation. In fact we use it as a purely therapeutic measure in cases of morphin poisoning, in cases of so-called traumatic or toxemic shock,[19] and wherever the respiration is feeble.[20] Oxygen can be given much more effectually and cheaply by the use of rebreathing than in the ordinary way. Thus with anesthetics of low toxicity and the use of rebreathing we can sometimes actually benefit a very ill patient by an anesthesia.

On the other hand, when we give ether by the open method we take a very efficient means of producing acapnia, because ether diminishes the formation of carbon dioxed by the tissues, and by stimulating the respiration hastens its elimination as well. Symptoms of a mild grade of acapnia under open ether anesthesia are common. Thus a patient who has perhaps been difficult to anesthetize or who has been lightly under ether for some time and is breathing at a rapid rate will gradually stop breathing. After an interval of perhaps two or three minutes his respiration will start again but will not be normal for a long time. This occurrence, though alarming, is usually followed by no harmful results. Of course hundreds of patients are etherized daily by the open method without developing symptoms of shock. What prevents a serious grade of acapnia in the great majority of cases? There are a number of things which do so. In the first place many anesthesias are of too brief duration for acapnia to develop. Then again there is frequently more or less obstruction to the breathing during narcosis, and this prevents acapnia. Likewise the slowing of the respiration which results from a preliminary hypodermic of morphin may protect from the same danger.[21] Finally, the so-called "open" method is usually not "open" at all, for the mask is so covered with towels or gauze that the patient does considerable rebreathing.

---

[18] After rebreathing 10 liters of oxygen for three minutes, I found it to contain 8.9 per cent. CO_2. Allowing for decreased CO_2 formation during anesthesia, it is probable that the percentage breathed by the patient is seldom above this.

[19] Patients with feeble pulse and respiration—so-called "shock" cases—should be made to rebreathe air in oxygen till their respiration is normal before breathing the anesthetic.

[20] Levi, Ettore: Studies on the Patho-Physiologic Action of CO_2 and on the Therapeutic Applications in Surgery and Medicine of Mixture of O_2 and CO_2, Estr. d. Rev. crit. di clin. med., 1910, xi, 30 and 31.

It is a pity that in a case like the following accurate determination of the amount of carbon dioxid in the blood could not be made, so that we could judge whether or not death was due to acapnia:

> The patient was a well-nourished middle-aged woman, with no disease of the heart or blood-vessels, on whom a colostomy and an excision of the rectum was done for a carcinoma. The anesthesia was by the "drop ether" method and was of two hours' duration and rather light. The patient's breathing was rapid and carefully kept free from obstruction. There was practically no loss of blood and but little trauma connected with the operation. The patient never regained complete consciousness, though she could respond feebly when spoken to. Her pulse was rapid and of poor quality; her temperature subnormal, her color slightly cyanotic and her respiration very feeble. She never rallied, and died eight hours after operation. An autopsy showed no apparent reason for death, which was attributed to surgical shock.

Is it not possible in this case that an acapnia had produced fatal injuries to the tissues in the manner described by Henderson?

Apart from the prevention of acapnia the form of anesthesia I have described has several other advantages over open ether anesthesia. The chief of these are three: (1) lessened postanesthetic vomiting; (2) decrease in number of cases of abdominal distention after operation; (3) practical abolition of postanesthetic lung complications.[22]

Vomiting after operation, of course, depends on many things besides the anesthetic. About 35 per cent. of our patients vomit, but the vomiting is usually very little. In looking over the special charts of 200 patients I found only four who had had more than very transient vomiting. Of the cases one was a case of exophthalmic goiter, one a case of stone in the common bile-duct, one a case of spreading peritonitis from an appendix abscess, and one a case of intestinal resection. The nausea alone seldom prevents a patient from taking water and nourishment at once after operation.

There has been very little experimental work on the question of abdominal distention following ether anesthesia. Cannon and Murphy[23] observed a great delay in the emptying of the stomach contents into the duodenum, and a slowing of the passage of food along the intestines after etherization. Figure 2, which is a tracing obtained from Dr. D. R. Hooker,[24] demonstrates the paralyzing effect of a weak ether vapor on the pyloric ring of the frog. It also shows that carbon dioxid acts as a powerful stimulant to the muscle of the ring. Of course the conditions to which the bowel was subjected when this tracing was obtained were abnormal, still the paralysis by ether is exactly what any clinician would expect. It is well recognized that an excess of carbon dioxid in the blood promotes peristalsis, and Henderson[25] has shown that the normal intestinal movements, which cease after a laparotomy, can be restored by passing a stream of carbon dioxid over the exposed bowel. These experimental results are confirmed by our clinical experience. It will be recalled that we use the smallest possible amount of ether, and produce a hypercapnia by making the patient rebreathe. In the 200 cases referred to above there was not a case of abdominal distention except after laparotomy, and among the laparotomies, seventy-five in number, it occurred in but three cases, these being the same patients who had considerable vomiting.

In 2,500 cases of gas-oxygen or gas-oxygen-ether anesthesia we have had but one case of postanesthetic pneumonia; this was in a girl with general peritonitis, who recovered. I am perfectly aware that this absence of pneumonia has been partly accidental, since pneumonia after operation may be due to causes other than the anesthetic. The record is, however, striking, and all the more so because we have anesthetized without hesitation, in cases of pulmonary tuberculosis, bronchitis and empyema. It contrasts markedly with the record after open ether. Here in a series of 400 cases we have had one death from ether pneumonia, and two deaths, one with autopsy, from acute pulmonary tuberculosis.[26] The latter patients were both operated on for tuberculous glands of the neck. Both patients died rather late — in from two to three weeks — after operation, but they ran a high temperature from the first. It was the opinion of Dr. L. V. Hammond, who has charge of the work on tuberculosis at the Johns Hopkins Hospital, that the etherization had lighted up small apical foci of disease undetected before operation.

[23] Cannon Movements of the Stomach and Intestines in Some Surgical Conditions, Ann. Surg., April, 1906, xlii, 513.

[24] I wish to thank Dr. Hooker for permission to publish this tracing and for the *following note:*

"Dr. Gatch has asked me to add a note covering some unpublished experiments done in the physiologic laboratory of the Johns Hopkins University, which appear to have a direct bearing on his own work.

"Cross-sections of blood-vessels or intestine, to which a recording lever was attached, were hung in a moist chamber. In the use of tissue from warm-blooded animals the temperature of the chamber was maintained constant at 35 C. Through the chamber were passed alternately streams of oxygen and carbon dioxid gas. By this method the tissue studied was exposed to practically pure atmospheres of the gases. The experimental conditions, therefore, did not fall within physiologic limits, so far as the percentage of gas is concerned. Work is now in progress to investigate the effect of different percentages of oxygen and carbon dioxid. Aside from the result of this future work, however, the interesting fact has been demonstrated that the musculature of the blood-vessels responds in atmospheres of the gases, studied in an exactly opposite manner to the musculature of the intestines. Carbon dioxid causes a marked improvement in the tone of the intestines and a marked relaxation of tone in the veins and arteries. On the other hand, oxygen causes a relaxation of tone in the intestines and an improvement of tone in the veins and arteries. These results were obtained in the case of both warm-blooded and cold-blooded animals and demonstrated with graphic records.

"If it be true that Henderson reasoned by analogy from the behavior of the smooth muscle in the intestine to that in the blood-vessel (especially the veins) in developing the acapnia theory of surgical shock, it is obvious from these results that his reasoning was not entirely justifiable.

"The correlation of the difference in action of these gases in physiologic economy tempts speculation. The body seeks to rid itself of any excess of carbon dioxid. Jerusalem and Starling (Jour. Physiol., 1910, xl, 279) have shown that carbon dioxid (0.625 of an atmosphere) increases the efficiency of the isolated mammalian heart chiefly by improving its diastolic relaxation. Bayliss (Jour. Physiol., 1901, xxvi, 32) has shown that this gas relaxes vascular tone. It has long been known that in the intestine the same gas increases peristalsis and Mall (Johns Hopkins Hosp. Rep., 1896, i, 37) has suggested that rhythmic movements of the intestines may help to empty the venous plexuses in the walls and thus aid in driving the blood into the portal system. We have, therefore, a coordination of activity which greatly facilitates the circulation of blood and the consequent rapid elimination of the carbon dioxid. Oxygen in excess, on the contrary, would tend to bring about opposite effects with a resultant retardation of the circulation.

"In conclusion, it should be clear to the reader that this is a chemical regulation of the circulation entirely peripheral in its action. The action of the gases on the medullary centers is a wholly different question."

[25] Henderson: Shock After Laparotomy, Its Prevention, Production and Relief, Am. Jour. Physiol., 1909, xxi, 60.

[26] Walsh: Chloroform Rather Than Ether Anesthesia in Tuberculosis, The Journal A. M. A., Aug. 28, 1909.

In closing I do not wish to leave the impression that this form of anesthesia is free from danger. It is without danger so far as postoperative effects are concerned. During the administration, however, there are dangers, though these can always be prevented by careful and skilful administration, and arise from causes which can generally be foreseen. The method should not be used except by those who have made a special study of its problems.

SUMMARY

1. Rebreathing, when properly regulated and when the oxygen supply is ample, is harmless and can be put to a valuable use.

2. If we can prevent anoxemia, overconcentration of vapor and too great a depth of anesthesia, we can obviate most of the serious objections to the closed method of giving ether.

3. The process of rebreathing prevents the elimination of ether and chloroform by way of the lungs, and overventilation of the lungs hastens the elimination.

4. It is suggested that after any administration of ether or chloroform, overventilation of the lungs be brought about by the use of mixtures of oxygen and carbon dioxid.

5. Morphin, or any drug which depresses the respiration, retards the elimination of ether or chloroform.

6. A method of administering nitrous oxid and if necessary ether with oxygen by the method of rebreathing is described and its advantages and dangers discussed.

Its chief advantages are (1) the rapidity and pleasantness with which anesthesia is established; (2) the ease with which any depth of anesthesia can be secured; (3) the prevention, to a very large extent, of postanesthetic vomiting, pulmonary complications and abdominal distention.

Its chief dangers are (1) anoxemia due to a failure to give sufficient oxygen or to an obstructed air-way; (2) impediments to the respiration, which in a long anesthesia may exhaust the patient; (3) with cardiac cases excitement during the period of induction.

[DISCUSSION ON THE PAPER OF DR. GATCH APPEARS ON PAGE 1611 OF THIS ISSUE.]

ANESTHESIA, WITH ESPECIAL REFERENCE TO NITROUS OXID AND ITS SEQUENCES

W. H. ALLEN, M.D.
First Lieutenant, Medical Corps, U. S. Army
FORT SLOCUM, N. Y.

It is desirable to call attention to two points of considerable importance in relation to anesthesia in general. The first of these is the need of all general anesthetics being administered, as far as possible, by or under the supervision of trained anesthetists. There can be no reasonable doubt that a very large proportion of the mortality from postoperative conditions, as well as from the anesthetic *per se,* is due to the unskilled administration of these powerful drugs. In its report, the Anesthesia Commission of the American Medical Association calls particular attention to this in the following words:

> From the statements set forth you will see something of the breadth and of the intricacy of the present-day problem of anesthesia. It is a striking fact that all the newer methods demand expertness, experience, and special apparatus.

The surgeon, moreover, should be relieved from all anxiety concerning and responsibility for the anesthetic in order that he may devote his undivided attention to the work in hand.

The second point is the necessity of selecting the anesthetic or combination or sequence of anesthetics suitable for the special condition to be met. On this point Hewitt says:

> Putting aside for the present certain exceptional circumstances . . . it may be said that the practice of employing one anesthetic for all cases must now be regarded as belonging to a bygone time. To insure success in inducing and maintaining general anesthesia we must vary our anesthetic and our methods of using it, according to the exigencies of the case with which we have to deal.

The anesthetist should make a careful study of the situation, not only with regard to the patient's temperament and physical condition but also in relation to the nature of the operation. This is particularly true of procedures on the head and throat, in which cases it is incumbent on the anesthetist to so plan his work as to offer the minimum of interference to the surgeon. After a due consideration of all factors, he should choose that anesthetic and method of administering it which best fulfils the indications. He should, however, at all times be prepared to abandon his prearranged scheme and adopt another should the exigencies of the case so require. Occasionally, a case will arise that will tax to the utmost the administrator's skill, ingenuity and armamentarium. As an example, I quote the following notes on a case observed while anesthetist to the Eye and Ear and South Side Hospitals, Pittsburgh, Pa.:

Patient.—Miss B., aged 22, suffering from some obscure stomach condition, characterized for the last ten days by constant vomiting after eating. Medium build; moderately anemic. Pulse 84, fair volume and tension. Chest negative, except for slight weakness of cardiac first sound.

Operation.—Exploratory laparotomy. The attending surgeon stated that on a recent occasion it was found impossible to produce complete anesthesia with the morphin-ether sequence (open method) and that the operation had to be abandoned after incision to the peritoneum, owing to signs of circulatory shock. The pulse ran high for ten days subsequently.

Anesthesia.—This was started with pure nitrous oxid, oxygen 2 per cent. being added after a few breaths and gradually increased to 6 per cent. Anesthesia was complete in about fifty seconds. Ether was now cautiously admitted. Apnea at once occurred, followed by profuse secretion of mucus, retching and slight vomiting; pulse more rapid, abdomen rigid. On stopping ether and increasing oxygen for a moment, former quiet anesthesia was restored. Apnea occurred at each attempt to add ether. Atropin gr. 1/100 was given to control mucus and as a respiratory stimulant. Owing to insufficient nitrous oxid to continue to the end of the operation, the patient was allowed to come out slightly and chloroform was administered by the open method for a few minutes to moderately profound anesthesia. Ether was resumed with 4 per cent. oxygen and a few breaths of nitrous oxid given from time to time when respiration lagged. Anesthesia continued uneventfully for two hours, extensive pelvic work being done through a second incision. Pulse varied from 100 to 120, being 114 at the end. There was prompt recovery without postoperative vomiting.

NITROUS OXID

While ether, either alone or as the terminal member of some sequence, will be the routine anesthetic, it is desirable to consider the properties of nitrous oxid.

MORTALITY RATES

The combined statistics of Julliard of Geneva and Ormsby of Dublin, covering 407,553 ether administrations, show a mortality of one in 16,302. For chloroform it is one in 3,162. Ethyl chlorid statistics are very scarce, but McCardie believes that the death-rate is about one in 3.000. Hewitt, in an extensive review, found only seventeen deaths directly traceable to nitrous oxid, recorded from 1860 to 1900. No deaths have been reported from nitrous oxid and oxygen. Ream. of Chicago, reports 30.000 administrations without a single accident; Teter, 12,000, 1,000 of these being for major operations lasting from one-half to three hours.

Nitrous oxid is therefore by far the safest general anesthetic known.

PHYSIOLOGIC ACTION

Nitrous oxid has a slightly sweet taste and its inhalation is accompanied by no unpleasant sensations. It produces anesthesia by *a direct action on the cerebral* cortex (Hare), though, when given pure, the anoxemia is probably a contributory factor. Complete anesthesia occurs in from fifty to sixty seconds and lasts for from thirty to fifty seconds. With oxygen the anesthesia can be prolonged indefinitely. Claude Lyons administered nitrous oxid with 15 per cent. oxygen to a dog for three consecutive days. Recovery occurred in fifteen minutes and there were no appreciable after-effects. Clinically, recovery occurs almost as soon as the mask is removed.

The anesthesia is much lighter than that of chloroform or ether and the patients are usually not so tranquil or completely relaxed. In favorable subjects, with proper percentages of oxygen, normal sleep is closely simulated. It is rarely followed by nausea or vomiting.

Careful studies by Kemp show that there is no direct effect on the heart and vasomotor systems, but here also a rise of arterial pressure is caused by the slight intercurrent asphyxia.

As the result of recent work concerning its effect on the blood, Hamburger and Ewing conclude that nitrous oxid produces no permanent or surgically significant changes, while ether and chloroform both produce slight anemia. Chloroform causes, in addition, hemolysis.

Respiration is primarily stimulated, but unless air or oxygen be admitted, it is secondarily depressed and finally ceases from muscular spasm. These phenomena are purely asphyxial and are avoided by suitable percentages of air or oxygen. Slight cyanosis is commonly an accompaniment of its administration, but is to be disregarded.

No changes in any of the body structures have been demonstrated. It has been thought that the use of this drug produces temporary glycosuria, but recent studies render this extremely doubtful (Hare).

INDICATIONS

It should be employed in all cases in which chloroform and ether are contra-indicated. Bevan urges its employment on account of its greater safety, absence of unpleasant symptoms, the little or no resulting nausea, and its rapidity of action. He asserts that it is the anesthetic of choice for the reduction of fractures and dislocations; for the opening of felons; for breaking up adhesions in joints; for draining empyemas and lung abscesses; for exploratory laparotomies and gall-bladder work; for nephrotomy, nephrectomy and nephrolithotomy; for bladder work, such as suprapubic lithotomy and prostatectomy; for draining appendiceal abscesses; for colostomy, gastrostomy and enterostomy; for the repair of typhoid perforations and for gastric and duodenal ulcers; in hernia operations, especially for the relief of strangulated hernia; for varicocele and open operations for hydrocele; in castrations; in amputations except at the largest joints; and in removing such growths as fatty tumors.

CONTRA-INDICATIONS

On account of its asphyxial tendencies with consequent venous congestion, increased blood-pressure, and muscular spasm, pure nitrous oxid should not be employed: in cases with narrowed or obstructed air-passages, as in association with hypertrophied tonsils, goiter, etc.; in cases with extremely bad hearts from either valvular or myocardial disease; in very young children; or in advanced arteriosclerotics.

These contra-indications may all be met by the administration of suitable percentages of oxygen.

ADVANTAGES

1 Safety at time of administration and later in absence of respiratory, circulatory, or nephritic complications or acid intoxication.

2. Rapidity.

3. Comfort of patient both in induction and absence of postanesthetic vomiting.

DISADVANTAGES

1. Narrow zone of anesthesia with consequent uncertainty of muscular relaxation and freedom from reflex movements.

2. Necessity of skill in administration. (This cannot be considered a valid objection.)

3. Cost of apparatus and of gases (from $4 to $6 per hour for the latter).

ADMINISTRATION

This is conducted by means of some form of special apparatus, the exact technic depending on the one employed. Satisfactory ones have been devised by Hewitt, Gwathmey, Cunningham; Teter, etc., the principle of all of them being the same. I employ Teter's.

Air is less applicable than oxygen for employment with nitrous oxid, on account of the large percentage of inert nitrogen which it contains. The administration is usually conducted with pure nitrous oxid for the first thirty or forty seconds, oxygen being then admitted and gradually increased. Generally speaking, from 4 to 6 per cent. of oxygen is applicable for men and from 6 to 8 per cent. for women and children, though the variations may be within wide limits, the indications being to avoid cyanosis and jactitation on the one hand and restlessness and talking on the other.

SEQUENCES

For routine use, I employ the nitrous oxid and oxygen-ether sequence. The advantages are as follows:

1. Greater safety than ether alone on account of lessened amount of ether inhaled and elimination of stage of excitement, in which many of the reported fatalities have occurred.

2. Saving in time, the patient being unconscious in forty or fifty seconds, and usually in third ether stage in three or four minutes.

3. Much pleasanter for patient in induction and in lessened postanesthetic vomiting. The latter is probably due to lessened swallowing of ether-laden mucus during induction.

4. With the Teter and Cunningham apparatus there is, in addition, less liability to ether bronchitis and

pneumonia and surgical shock on account of the inhalation of warmed and thoroughly mixed ether vapor; and lessened consumption of ether, owing to the inhalations only passing through it.

The nitrous oxid and oxygen-ether-chloroform sequence may be employed to eliminate the dangerous induction period of chloroform anesthesia, when it is desirable to employ that anesthetic.

SURGICAL PATHOLOGY OF THE PROSTATE

REVIEW OF 468 CASES *

LOUIS BLANCHARD WILSON, M.D.
AND
BERNARD FRANCIS McGRATH, M.D.
ROCHESTER, MINN.

We have recently reexamined the specimens and reviewed the data from all cases of operations on the prostate in this clinic from Oct. 28, 1904, to June 1, 1911. The series, comprising as it does 468 cases, is large enough to warrant placing the observations on record for comparison with the conclusions of previous observers.

Since the publication of the studies of Young, Geraghty and Stevens in 1906, the only comprehensive memoir which has appeared is that of von Frisch, last year. Therefore, we have discussed elsewhere the subject of the prostate, some what at length, deeming it advisable to review therein the essential points in the anatomy and the physiology as well as the pathology of the gland. In thus adding to our own observations a somewhat full review of the data and discussions of others concerning the normal and the pathologic conditions of the prostate, we have hoped not alone to stimulate interest in this organ, but also to place in convenient form the more important facts and theories concerning it, as a basis for future studies. Herein we shall confine ourselves to a somewhat brief recital of the main points in our paper, referring the reader elsewhere for the more detailed discussion of them.

ANATOMY

During the third month of fetal life the mesoblastic tissue surrounding the lower ends of the Müllerian and Wolffian ducts becomes differentiated in association with a thickening of the wall of the primitive urethra. Simultaneous with this the epithelium of the sinus urogenitalis throws off three groups of buds (Pallin) on each side. These buds consist initially of solid cordons of epithelial tissue which penetrate into the annular mass of mesoblastic tissue surrounding them. The glands do not acquire a lumen until after birth.

Shape.—The prostate is, geometrically, an oblate conoid, flattened dorsoventrally, with its base upward and its apex resting on the triangular ligament. The transverse diameter is usually 1/5 to 1/4 more than the base-to-apex diameter of the gland.

Weight.—For comparative purposes, all adult prostates weighing under 16 gm. may be considered abnormally small, all weighing from 16 to 24 gm. normal in size, and all weighing 24 gm. or more as abnormally increased in size.

Subdivisions.—From the posterior aspects the prostate is a bilobular bilaterally symmetrical organ. In its posterior border is a notch, from which a palpable groove extends to the apex, marking the course of the urethra. The slightly convex lateral lobes lie to the right and left of this groove.

In our unabridged article we have discussed rather in detail and presented the illustrations of Tandler and Zuckerkandl's recent contribution on the important question of prostatic hypertrophy. In an especially adapted and extensive series of cases these investigators have demonstrated that hypertrophy of this gland always begins in the *middle lobe,* that total hypertrophy never exists, since atrophy is also present, and that the *surgical capsule* is composed of prostatic tissue. Consequently, prostatectomy is an *intraprostatic* procedure. Based on their observations, which showed that the hypertrophy always involved the portion of the prostate toward the bladder, Tandler and Zuckerkandl hold that operation through the bladder-route is the method of choice. A description of the technic from the anatomist's standpoint is also given.

The verumontanum, or colliculus seminalis, is a long elevation, about 3 mm. high, composed mostly of cavernous tissue and situated near the middle of the posterior wall of the pars prostatica urethræ. It declines at both ends, and on its anterior reclivity is a fine slit-like opening, the exit of the uterus masculinus.

The uterus masculinus is a pear-shaped, longitudinal pouch, extending upward and backward to the base of the prostate, and ending between the ejaculatory ducts. Normally it is 10 to 12 mm. in length, lined with mucous membrane and surrounded by a circular layer of muscle.

The ejaculatory ducts, which transmit the secretion of the seminal vesicles, pass obliquely through the prostate from above, opening into the pars prostatica urethræ dividing it into a proximal and distal portion.

Relations.—From a pathologic standpoint the more important relations of the prostate are the following: (a) the base is in intimate contact with the floor of the bladder; (b) the posterior surface is separated from the rectum by only sparse tense, cellular tissue, poor in fat; (c) the body of the gland embraces a considerable portion of the urethra (pars prostatica urethræ); (d) it communicates with the seminal vesicles and the ejaculatory ducts; (e) it likewise communicates through the vas deferens with the epididymis and the testicles.

Structure.—The prostate possesses a fine fibromuscular capsule of its own which is firmly adherent. It completely invests the gland, and sends a median septum inward, which surrounds the urethra and gives off a number of thinner partitions which divide the parenchyma of the gland into about forty lobules.

In addition, the organ is fixed in its position by fibrous tissue which has been designated by A. Retzius as the "ligamentum pelvio-prostaticum capsulare." This possesses partly the form of an envelope and partly the structure of band-like strips spreading into the enveloping portion and connecting the prostate with the pubis (the ligamentum puboprostaticum).

The visceral layer of the pelvic fascia, first described by Desnonvillers, is lifted up from the pelvic fascia laterally and posteriorly, appears as an application—Waldeyer—of this fascia, on the prostate. From this it passes over the bladder, enclosing the upper surfaces of the plexus pudendalis, the plexus vesicoprostatici, the seminal vesicles, and the ampulla of the ductus deferentes. Between the rectum and the prostate the sapsule is strongest.

The muscular element of the prostate is made up of unusually fine, unstriated fibers. The second sphincter muscle (sphincter vesicæ [Henle], sphincter prostaticus

---

* Abridged from an article read in the Section on Pathology and Physiology of the American Medical Association, at the Sixty-Second Annual Session, held at Los Angeles, June, 1911.

* From the Laboratory Department, St. Mary's Hospital, the Mayo Clinic.

[Kohlrausch]) is formed of striated as well as smooth muscle-fibers. Striped muscle-fibers also pass between the two sphincters on the anterior surface of the prostate. In the interior of the gland the muscular element is a dense fibromuscular mass surrounding the urethra. Through this mass pass the prostatic ducts. Spreading out from it in all directions are muscular bands consisting of transverse and longitudinal fibers. While these usually follow the connective tissue framework, in many places they form by themselves the interalveolar septa without admixture with any discernible fibrous tissue. Here and there they form circular or looped structures which embrace the gland lobules. Frisch holds that it is the smooth muscle of the prostate proper which forms the sphincter vesicæ internus.

The parenchyma of the prostate consists of from fifteen to thirty-two distinct glandular systems, each opening by an independent excretory duct into the urethra. Some anatomists describe these gland units as terminal and others as an alveolar type. The terminal alveoli are found scattered throughout the gland, so that a section at any level shows both alveoli and ducts.

We have never seen a tunica propria about any of the alveoli, which agrees with the observations of other recent workers. Instead, the epithelium rests directly on the smooth muscle or fibrous connective tissue.

While in the alveoli of the adult prostate, a double layer of epithelium is frequently encountered, it is an open question whether such a formation is normal or not. Langerhans says: "In all alveoli a double layer of cylindrical epithelium is present."

The cylindrical epithelium lines the glands throughout except near the orifices of the ducts where transitional epithelium similar to that of the urethra is present.

Islands of lymphoid tissue are not infrequently found in the prostate. Weski, who has carefully studied these, notes their analogy to those found by Waldeyer in the dog's prostate. He mentions the possibility that the structures may be pathologic, but believes, on account of the entire absence of other evidences of inflammation in the same glands, and on account of the known presence of similar lymph follicles in other glands, that they may be considered physiologic.

The arteries arise principally from the inferior vesical artery. A few small branches also arise from the middle hemorrhoidal and internal pudendic arteries. They enter the periphery at numerous points, penetrate the gland and divide, forming a close capillary meshwork within the alveolar walls.

The veins form a rich plexus within the gland tissue and around the ducts. They emerge from the organ laterally and pass in part into the rich plexus within the capsule, and in part beneath the mucous membrane in the region of the orificium internum and the colliculus seminalis. Bordering on the anterior surface of the prostate, behind the ligamentum arcuatum pubis and under the edge of the symphysis pubis is the plexus pubicus impar, which receives not only the blood from the prostate, but also from the deep dorsal veins of the penis, communicates with trunks from the bladder, seminal vesicles and rectum and is continued as the prostatovesical plexus to the internal iliac veins.

The lymphatics form a wide-meshed network on the surface of the gland. Within the organ they are richest at the base and most sparse at the apex. Compared with the blood-vessels their course is surprisingly tortuous. The lymphatic plexuses on each side form two trunks, a superior and a lateral. The superior pass to the obturator lymph-nodes of the pelvis and the lateral to the internal iliac lymph-nodes (Sappey). The endothelial cells of the lymphatics are characterized by a very finely granular protoplasm.

The nerves of the prostate take their origin from the inferior hypogastric plexus of the sympathetic. The organ is richly supplied with nerves and contains, chiefly on its periphery, ganglion nodes, numerous isolated ganglion cells and a great number of variously constructed end-organs. As a delicate plexus they pass from the seminal vesicles. In this plexus are present fibers from the anterior roots of the third and fourth sacral nerves.

The nerve end-organs on the outer surface of the prostate have been known for a long time. In the mucous membrane of the pars prostatica, von Planner has found numerous bulbous nerve-endings which are situated in the more superficial layer of the membrane and which are sometimes plainly visible as elevations. The recent elaborate and painstaking studies of Timofeew have shown that the prostate contains a most complicated system of nerve-fibers and nerve-endings.

PHYSIOLOGY

In order to appreciate the physiology of the prostate three points must be considered: first, its function as a secreting gland; second, its muscular apparatus, particularly the sphincter formation; and third, its extraordinary wealth in nerve-fibers, ganglion cells and nerve end-organs.

As a secreting gland the prostate undoubtedly belongs to the sexual organs. The secretion of the prostate is a very essential factor of the spermatic fluid. Up to the time of puberty the gland undergoes a rapid growth and reaches its complete development only after that time. After the loss of the testicles in childhood the gland is arrested in its development; after castration of the adult it becomes atrophied.

Casper's work with dogs of the same litter showed that double-sided castration resulted in all cases in a marked diminution of the prostate and most decided changes in its glandular structure. Neusser notes that the persistence of the prostatic secretion, in many cases for a long time after castration, and the actual power of coition in the eunuch, which is lost only after years, indicate that an independent function must be attributable to the prostatic gland or to the innervating apparatus. Fürbringer has shown that the so-called "Böttcher" or "spermatic crystals" arise from the prostate. He succeeded in demonstrating the crystals by evaporation of the prostatic secretion secured from fifty-six autopsies (90 per cent.).

Besides the Böttcher crystals one finds constantly in the prostatic secretion large, colorless, moderately refractive, round granules. These produce the milky cloudiness and, judging by their reactions, consist chiefly of lecithin. The filtrate contains albumin but no mucin.

Spermatic crystals are not present in prostatic secretion secured by rectal palpation of the living. Ammonium phosphate, however, added to such expressed secretion causes the formation of the crystals. Fürbringer therefore concludes:

> For the formation of the Böttcher crystals observed in the ejaculated spermatic fluid, the secretion of the prostate affords the basic portion, whereas the phosphoric acid necessary thereto is contributed by the other components of the spermatic fluid.

In the dead body the post-mortem degeneration of the epithelium probably furnishes the necessary phosphoric acid. The characteristic spermatic odor is probably an attribute of combinations of the Schreiner base in dissolved form. Fürbringer demonstrated that the secretion of the prostate causes the normally motionless spermatozoa, as they are stored in the seminal tract, to become motile.

The descriptions found in the literature of the appearance of the prostatic secretion as clear, glossy, thready, etc., are incorrect, as Fürbringer explained. The secretion is a thin fluid of milky cloudiness, slightly acid or neutral in reaction and of a highly characteristic odor.

Percy has shown that spermatozoa quickly die in contact with uterine mucosa without the admixture of prostatic secretion, while in the presence of this secretion they remain alive three to eight days. Steinach has pointed out that simultaneous extirpation of the seminal vesicles and the prostate, while not interfering with the power of copulation, nullifies the capacity of begetting.

That the prostate possesses an internal secretion which acts on the external secretion of the testicles, vas deferens and the seminal vesicles, is strongly suggested by the work of Serralach and Parès. They found that after the removal of the prostate from dogs the secretion of all the sexual glands ceased, spermatozoa were no longer to be found and the testicles became atrophied. When injections of glycerin extract of the prostate were made after the prostatectomy, atrophy of the testicles did not occur, ejection remained, and spermatozoa were demonstrable in the ejection.

The arrangement of the smooth muscles of the prostate, longitudinally about the glandular tubules and circularly about the alveoli, is such that their contraction empties the gland of its accumulated secretion. According to Lusena, the quantitative relation of the muscles and glands of the prostate varies according to the age of the individual. In middle life the muscles and glands are present in the same amount. In old age the muscles are developed at the expense of the glands. Between 25 and 30 years of age the genital activity of the prostate reaches its highest point. Between 45 and 50 years the fibromuscular layer becomes relatively more extensive, a sign of beginning age.

The mechanism of the bladder closure and the emptying of the urine may be properly ascribed to the sphincters of the prostate, Rehfisch and Posner to the contrary notwithstanding. The closure of the bladder is cared for by the smooth sphincter internus muscle which remains in a state of tonus. This tonus must relax when there is need to pass urine and then the effect of the detrusor muscle comes into action.

Frisch calls special attention to the fact that while the unstriated muscles of the internal sphincter may be the usual mechanism for closing the bladder, yet the auxiliary muscles of the perineum can assist in producing the same effect by an energetic voluntary contraction, a fact which is important in prognosis after prostatectomy.

It is probable also that the numerous ganglia situated in the prostate and bladder hold an important function in the closure of the latter and in urinary discharge, and that these must be looked on as centers.

In regard to the nerves of the prostate all the motor and vasomotor fibers in the nervi erigentes and nervi hypogastrici, which arise from the inferior mesenteric ganglion, reach the prostate. Stimulation of the erigentes has a negative result, or, in the beginning, the excretion of a considerable amount of secretion, which is then followed by a cessation. On the contrary, stimulation of the hypogastrici produces a continuous, genuine secretion. If a cannula be introduced into the urethra in connection with a long upright tube, the level of the fluid mounts rapidly upward through stimulation of the nervi erigentes and sinks again downward as soon as the stimulation is suspended. Under similar conditions, if the hypogastrici be irritated, then the entire tube becomes filled and the fluid flows out from above. The erigentes, therefore, only press the secretion out of the gland, which secretion has been produced by the stimulation of the hypogastrici, so that these are the real secretory nerves. Stimulation of the central stump of one of the hypogastrici, with its fellow intact, produces secretion, and does this even when the inferior mesenteric ganglion has been separated from the remaining sympathetic fibers and, consequently, separated also from the central spinal cord.

PATHOLOGY

INFECTIONS OF THE PROSTATE

1. Acute Prostatitis.
    - A. Catarrhal.
    - B. Follicular.
    - C. Parenchymatous.

    (Segond's classification; also held by Guyon).
2. Chronic Prostatitis.

Etiology.—As idiopathic primary processes they are rare and, excepting as complications of gonorrhea, infrequent.

Causes attributed by various authors are: from without, injuries due to horseback riding, bicycle riding and similar exercises; from within, unsuitable introduction of instruments, too frequent and unclean catheterization, lithotripsy, abortive injections, too severe cauterization of the pars prostatica (especially with the pencil — Guyon), unnecessary duration of the self-retaining catheter, caught stones and foreign bodies, stricture of the urethra.

Disposing causes are: congestions and irritations in the rectum (hemorrhoids, foreign bodies, fissures, fistulas, proctitis and periproctitis), chronic obstipation, dysentery and enteritis, venereal excess, masturbation, coitus reservatus, metastases in pyemia, typhus, measles, small-pox, croupous pneumonia, parotiditis, influenza, tonsillitis, carbuncle, furuncle, phlegmonous angina, gout, syphilis, cystitis, stones in the bladder, prostatic hypertrophy, and infection by way of the blood.

By far the most frequent cause is gonorrhea. Prostatitis can follow not only every acute gonorrhea of the posterior urethra, but also every stage of chronic gonorrhea. The older the latter, the more frequently will the prostate be found diseased. Whereas the infection is usually from the posterior urethra, many admit its possibility from the anterior urethra—perhaps by way of the lymph channels. Opinions as to the frequency with which prostatitis follows gonorrhea vary within wide limits. These differences are explained as probably due to errors and difficulty in diagnosis; those holding high percentages including in their statistics the mild, but more frequent cases; and those quoting low percentages limiting their diagnoses to severe parenchymatous prostatitis alone. The weight of evidence, however, appears to favor the opinion that prostatitis is a frequent complication of gonorrhea.

In our series of 468 cases, seven were tuberculous. Tuberculosis of the prostate is principally a disease of the young adult, though our meager list of cases does not show it.

With regard to its etiology it is highly improbable that heredity is a predisposing cause, though it has been suggested by a number of observers. It is also unlikely that

These neoplasms may be present in the gland both primarily and secondarily. Cancerous and sarcomatous nodules—the latter by far the more infrequent form—have been observed in cases in which the primary foci were situated in various organs. The primary tumor has been found most frequently in the rectum, less often in the urinary bladder, the seminal vesicles, on the penis, in the stomach (Engelbach), the lungs (Fenwick), and the dura mater. Kaufmann held genuine metastatic growths of the prostate to be extremely rare.

Malignancy in the prostate is observed from earliest childhood to late old age. Carcinoma is more prevalent in the latter decades of life, and sarcoma in the beginning years.

Of our patients
1 was between 40 and 50 years of age.
9 (12 per cent.) were between 50 and 60 years of age.
29 (40 per cent.) were between 60 and 70 years of age.
30 (41 per cent.) were between 70 and 80 years of age.

The middle period is relatively free from malignancy in this organ. The youngest patients observed were children 6, 8 and 9 months old (Rose, Socin, Bree). Since, undoubtedly, the beginning of development is to be dated much earlier, Klebs held as not unlikely that the process may at time be referred even to the intrauterine period of life.

Pathologic Anatomy: Of the seventy-three cases, fifty-one (69 per cent.) showed marked glandular hypertrophy, as was evidenced microscopically by papilliferous projections into the acini. In thirty cases (41 per cent.) there was definite muscular atrophy, and in sixty-one cases (83 per cent.) the fibrous stroma was increased. In ten cases (13 per cent.) there was no evidence of associated hypertrophy in the sections examined from the glands, leaving 87 per cent. in which there was evidence of hyperplasia. Whether in these cases the hypertrophy was primary and the carcinoma implanted thereon, it was impossible to determine, though in many *microscopic sections the apparent transition by almost* imperceptible variations from simple hyperplasia to undoubted carcinoma was observed.

Usually one can be moderately certain of the cancerous nature of the tissue on gross inspection alone. When the operator's knife, in making capsular incision, cuts through tense tissue which does not bulge, the edges of which are firm and ridged, suspicion should be at once aroused. It has been our experience that carcinoma in no tissue, with a possible exception of small tumors of the breast, removed at the surgical clinic was more apt to escape diagnosis grossly than that of the prostate, so that it is our inevitable custom to make frozen sections from various areas of the removed gland and report to the surgeon while the operation is in progress.

Etiology: The etiology of carcinoma of the prostate is completely unknown as is that of carcinoma elsewhere. Albarran and Hallé insist on a definite relationship between prostatic hypertrophy and carcinoma. Among eighty-six hypertrophied prostates they found, in twelve, changes in the epithelium, which they thought to be different grades of carcinomatous degeneration. When one considers the difficulty of accurate diagnosis, however, especially in cases of carcinoma of the prostate, all such instances as the above must be regarded with some suspicion, unless all of the tissue of the prostate was removed at the original examination and a careful microscopic investigation made thereof.

While we may consider it fairly well established that isolated epithelium, whether from inherent or external stimuli, exhibits a tendency to proliferate and infiltrate, and while the observations of many workers record series of pictures such as those described by Albarran and Hallé, yet we must be conservative in our interpretation of these *apparent transitional stages* of hyperplasia into carcinoma. Likewise, we must examine most critically all clinical data, such as the observations of Prédal and others, suggesting the same line of development.

Metastases: Many prostatic carcinomas show a marked tendency to seize on neighboring structures, particularly the floor of the bladder, seminal vesicles and rectum. The lymph-glands in the region of the prostate are the first to become infiltrated with cancer. After that, the retroperineal and inguinal glands become involved. Metastases to distant organs are common, and should always be as carefully as possible excluded in clinical examination before operative procedure. They are frequently present in the lungs, liver, spinal column and long bones. Von Recklinghausen, Sasse, Brown, Kolisko, Frisch and others have emphasized the importance of *seeking for small carcinomata in the prostate, breast* or thyroid in cases in which extensive metastases in the bones have been found at autopsy. Von Recklinghausen says:

> If, in the female, cancer of the vertebra breaks forth with unspeakable pain, as a rule, one does not err if he assumes the original focus to be in the breast. In such cases the primary focus may reach only to a very small size.

Frisch says:

> Perhaps just as frequently may the causative rôle for general carcinoma in man fall to the lot of prostatic cancer as to the lot of the breast-gland cancer in the female. We know how difficult it is to recognize prostatic cancer with the naked eye, how little it destroys the tissue, how very much more it tends to produce induration so that only the typical involvement of regional lymph-glands discovers and facilitates the diagnosis.

As prostatic sarcomata develop they involve the bladder wall and neighboring structures. The neighboring lymph-glands are usually affected, but distant lymph-glands rarely. Metastases to other distant organs — lungs, liver, etc. — are also uncommon, though instances have been reported.

With regard to the histologic type of tumor, the round cell is the most common, and after this the spindle cell. Angio-, lympho-, myxo-, adeno-, enchondro-, leiomyo-, and rhabdomyosarcomatous forms have also been reported.

In concluding this incomplete review of an important subject, we trust, that, at least, our aim to stimulate keener interest in the study of the prostatic gland has been successful. It is a regrettable fact that many otherwise well-informed physicians seem to be almost unaware of the existence of this organ. At least they are prone to ignore its rôle in the production of a train of symptoms which they frequently ascribe to a "weak bladder" or "kidney disease." Often patients die of the sequelæ of prostatic hypertrophy, or directly from prostatic carcinoma, without ever having had a rectal examination. Patients have been operated on for chronic appendicitis when their symptoms were really due to carcinoma of an unexamined prostate. In every case of gonorrhea in the male the possible involvement of the prostate should be remembered and the patient warned, at the time, of the troubles probably in store for him in the future.

A rectal examination should be a routine procedure with all males presenting themselves for diagnosis of *obscure abdominal as well as genito-urinary troubles.*

A CASE OF HYPERIDROSIS UNIVERSALIS WITH CONTINUOUS FEVER*

HENRY HERBERT, M.D.
LOS ANGELES

History.—The patient, E. Gr., 22 years of age, clerk, is the only child of his parents, who are living and healthy. As a child he had measles and some lung disease, otherwise he was healthy up to the age of 12, when his present ailment of constant sweating commenced. He lived formerly in the Middle West, came four years ago to Los Angeles, worked three years as a bell-boy in a hotel and has for the last year acted as bank messenger, having sought the occupations of bell-boy and clerk as being most suitable for his condition.

He perspires continually and the perspiration stops apparently only when he is in fresh air or in a draft; during sleep it stops only when he is exposed to a draft and fully uncovered. His perspiration increases indoors, in the theater, in church or by sitting still, and by exposure to the sun; he perspires also during rain or snow; his condition is aggravated after meals, after drinking cold water or warm drinks. His appetite is and always has been good, but he drinks a great deal of water. His bowels are regular; he looks normal and healthy. A peculiarity about his sweating is that the suprascapular and occipital region of both sides remain always dry (anidrosis).

His weight has for the last two years been about 120 pounds; for four years his temperature ranged from 99 to 102 F., and the following data were recorded by me at various times:

		Temp. F.	
Feb. 6, 1909,	2 a. m.	99.4	
" " "	8 a. m.	99.2	
" " "	3 p. m.	100.0	
May 1, 1909		99.6	
June 1, 1909,		101.0	
Sept. 28, 1909		99.2	
February, 1910		99.2	
March, 1910		100.4	Pulse, 96-120
May 26, 1911		99.8	Pulse, 108
June, 1911		99.0	Pulse, 96

He complains of weakness, inertia and nervousness; on deep inspiration he has vertigo; in throwing back his shoulders he feels numbness and formication over the dorsum of the two last fingers of both hands. Occasionally, he sees black spots dancing before his eyes, becomes dizzy, and in the past has had attacks of amaurosis. His knee-reflexes in 1909 were hardly perceptible. They are promptly elicited in 1911.

His blood was examined May 5, 1909, by Dr. Eleanor Seymour of Los Angeles, and revealed the following interesting facts:

Hemoglobin	90	per cent.
Red blood-corpuscles	6,040,000	
White blood-corpuscles	10,280	
Neutrophils	53	per cent.
Lymphocytes	21	per cent.
Eosinophils	14.5	per cent.
Large mononuclears	10	per cent.

Quite different are the findings by Dr. D. C. Ragland, of Los Angeles, June 28, 1911:

Red cells	5,700,000	
White cells	7,600	
Polymorphonuclear leukocytes	48	per cent.
Small lymphocytes	38	per cent.
Large lymphocytes	9	per cent.
Eosinophils	3	per cent.
Mast-cells	1	per cent.

Examination.—The ophthalmic and cutaneous tuberculin tests were negative. The examination of the urine proved to be negative; chest and abdomen apparently normal. On pressure over transverse processes of the sixth or seventh vertebra of both sides, I elicited considerable pain in the patient.

Pressure on the third sympathetic ganglion, or irritation of it causes hyperidrosis; paralysis or destruction of it causes anidrosis. In our case we had hyperidrosis, probably due to pressure, and partial anidrosis, probably due to paralysis of the respective nerves.

Profuse sweating has been caused by irritation of the cervical sympathetic in animals. According to Riehl, hyperidrosis may just as well be explained by the irritation of the vasodilators as by paralysis of the vasoconstrictors.

Friedlander reports observations by others of unilateral hyperidrosis, in diabetes mellitus, in general paralysis, temporary dementia, in mental diseases, in hemiplegia, in tabes, etc.

Many cases of unilateral hyperidrosis have been reported in otherwise healthy persons. In some individuals, hyperidrosis universalis occurs often, but only for a brief period; in others it is habitual and continuous. As a morbid function of the skin it usually lasts many years and is found almost exclusively during middle life. The immediate cause of the hyperidrosis is always located in the capillaries of the integument, especially of the coil glands and papillæ.

These conditions are regulated by the vasomotor (sympathetic secretory) nerves. We may thus understand how a profuse secretion of sweat, either general or local, may appear under the influence of mental excitement, fright, confusion, or local pains, as the result of a stimulus which is either reflex or starts from the central organs. This has also been shown experimentally. On making a section of the cervical sympathetic, Claude Bernard found that the vascular paralysis was associated with profuse perspiration in the paralyzed parts.

In one case of hyperidrosis of the left side of the body, Frankel and Ebstein found stasis of blood-globules in the vessels of the corresponding cervical sympathetic. In one case, which affected the left side of the head, Riehl noted, in addition to the same findings in the vessels, interstitial cellular infiltration of the superior ganglion of the cervical sympathetic.

Disturbances in the sympathetic of the neck are still obscure, and most of the lesions described in literature are spoken of as lesions of the sympathetic of the neck. Such lesions, affecting probably the superior ganglion or the whole length of the sympathetic, must differ in their clinical manifestations from isolated or strictly localized lesions. It seems that in the present case there is no disturbance of the superior or middle ganglion as the respective ocular symptoms are wanting. On the other hand, it has been proved experimentally as well as by autopsy that lesions of the inferior ganglion may produce symptoms as present in that case. In general, we will find lesions of the inferior ganglion produced by exostoses, aneurysmal tumors pressing on ganglion, or by inflammatory conditions in and around the ganglion.

1524 Magnolia Street.

ABSTRACT OF DISCUSSION

Dr. James T. Fisher, Los Angeles: I had the pleasure of examining this gentleman in my office a year or year and a half ago. He attracted a great deal of attention and the case was brought before our county medical society. At the time I examined him his physical condition was absolutely negative with the exception of the symptom that you see here—the sweating. His pupillary reaction was normal; his knee-jerks were not normal. In view of the fact of his age, and various factors which I will not go into, to me it is fairly evident that this man is suffering from an ordinary form of hysteria, and I am not inclined to think that it is other than that. Perhaps you will say that that does not explain all of his symptoms. Even so, I cannot account for this condition except as coming under the general classification of ordinary hysteria.

---

* Read in the Section on Nervous and Mental Diseases of the American Medical Association, at the Sixty-Second Annual Session, held at Los Angeles, June, 1911

Dr. Harold N. Moyer, Chicago: This appears to be a new find, or is at least a very rare symptom-grouping. With such exceptional findings a certain degree of modesty in suggesting a diagnosis is becoming. There are certain salient symptoms which are not explainable under any theory that I know of regarding the association of symptoms: First, the sweating; second, the presence of six million red cells; third, a marked eosinophilia; and fourth, a persistently elevated temperature. These make a symptom-grouping that I have never seen associated. The case presents a new combination of symptoms, and possibly a new disorder.

Dr. George A. Moleen, Denver: I have been very much interested in this case, but from the start it appeared to me on a functional basis. Someone has said that nothing could be present in hysteria but what could be produced by suggestion. I would like to ask if suggestion has been used in this case as a means of differential diagnosis. It has come within the experience of men who have used hypnotic suggestion that it is quite easy to produce either localized or general sweating to influence the temperature and produce other changes of equally remarkable natures. However, that would not account for the blood changes which occur in this case. The absence, however, of organic symptoms, or symptoms of tissue change, and the fact that the functional disarrangement which would produce or lead to the sweating can be reproduced by suggestion, lead me to believe that it is on a functional basis.

Dr. F. E. Murphy, Kansas City, Mo.: May I ask when this estimate of eosinophils was made?

Dr. Henry Herbert: Last year.

Dr. F. E. Murphy: Fourteen per cent. of eosinophils is certainly a symptom that necessitates some consideration. It would be interesting to know the percentage of eosinophils at this time. Possibly a year ago there was an intestinal parasite or something of that sort giving eosinophils. It would be interesting to know at this particular time how much the symptom observed a year ago is evidenced. There is one feature I observed, and that is the condition of this boy's vascular system. Several of us palpated his blood-vessels, and there are certainly marked changes in them. I am disposed to believe that there is something more than functional trouble in this instance.

Dr. Henry Herbert, Los Angeles, Cal.: The temperature was taken regularly and always by the mouth for a period of from two to five minutes. Suggestion has not been used in this case. In regard to the eosinophils, that suggestion of reexamining the blood of the patient is a very good one. I am at a loss to say what the diagnosis is. One interesting feature leads me to believe that it is a lesion of the third sympathetic ganglia: first, the intense pain on pressure; then, the accepted rule, or accepted experiment or experience, that irritation of the sympathetic ganglia, especially of the third on one side shows a unilateral sweat, whereas the paralysis of that center shows anhidrosis. Now, we have general sweating on both sides, pain on both sides on pressure over the third sympathetic ganglia. At the same time, over that ganglia in that approximate region, or the region which is supplied by the approximate nerves, there is anhidrosis—no sweating at all. That would indicate a general irritation of the sweating center and a paralysis of those nerves supplying that area—the suprascapular region. If there is any process, fibrosis or chronic inflammation, to furnish the ganglia with some pressure, that would account for that anhidrotic area, and at the same time irritation of the entire sympathetic ganglia. The symptom-grouping, as one of the speakers mentioned, with the eosinophils, speaks against the supposition of a functional disorder or hysteria. I think that symptom is based on a permanent disorder, probably a disorder of the nervous system

HOW OUR THERAPEUTICS CAN BE IMPROVED *

BOARDMAN REED, M.D.

LOS ANGELES

Tremendous advances have been made in therapeutics during the past two decades, advances which it is needless to enumerate to educated medical men. But there remains yet room for improvement. There are still failures in treatment, many of which could be avoided by a more perfect mastery of all the conditions which confront those charged with the high duty of endeavoring to heal the sick. This can be attained only by raising the standard of the doctorate to a yet higher plane, so as to assure for every practitioner a better knowledge of all that pertains properly to the science and art of healing and the auxiliary medical sciences, together with clinical experience under instruction. Such a training with industry and patience would assure an accurate diagnosis in every case in which such a diagnosis is practicable, followed by the best possible treatment.

Improvement must result from a more thorough study of (1) man and his organs and functions in both health and disease, including especially diagnosis; (2) a more intimate acquaintance with all the reliable remedies, medicinal, mechanical and psychologic from whatever source, a knowledge which shall recognize the fact that the more active ones seem to be capable of exerting either of two opposite actions according to the dose.

A very large proportion of the failures in treatment, whether made by regulars, sectarians, quacks, counter-prescribers or self-dosers, is due to a wrong diagnosis. No method of treatment is likely to prove helpful when prescribed in the wrong case; very frequently then it does harm. Innumerable patients die because the diagnosis is made too late, the medical attendant not having obtained needed counsel in time. Other failures and often much mischief result from continuing too long and in large dose a remedy which may have done good at first. Sometimes the failure is in consequence of too small a dose having been prescribed. I have seen cases of hyperchlorhydria and ulcer of the stomach or duodenum aggravated by 10- or 15-gr. doses of sodium bicarbonate and yet afterward promptly relieved and finally cured with the help of teaspoonful doses of the same drug well diluted and combined, when necessary, with 30 to 40 gr. of bismuth.

On the other hand, while drop doses of the wine of ipecac will relieve some forms of nausea, and severe vomiting often yields to drop doses of Fowler's solution, *à la* Ringer, and a threatened miscarriage is stopped by the tincture of cimicifuga every hour in the same small dose, as I frequently proved in my general-practice days, any one who would try these medicines in the usual doses in such cases would surely aggravate them.

Evidently, then, it would be a gain to our therapeutics if medical students were plainly taught that tissue-disturbing drugs are capable of producing opposite effects according to the dose. This was demonstrated to my own satisfaction twenty-three years ago by a careful study of the elaborate reports of numerous experiments conducted by eminent pharmacologists in England and Germany especially. My conclusions, though questioned, have never been refuted. They were published first in the *Practitioner* (London), and afterward in this country. In a large experience since 1888, they have been amply confirmed. The matter was summed as follows:

---

* Read in the Section on Pharmacology and Therapeutics of the American Medical Association, at the Sixty-Second Annual Session, held at Los Angeles, June, 1911.

1. A relatively small dose always at first stimulates the parts (nerve-centers, nerves, glands, muscles, membranes or other tissues) which the drug specially affects.

2. A sufficiently large dose (pushed far enough) always finally paralyzes the parts which the drug specially affects.

3. A moderate or medium dose may first stimulate and afterward depress, finally paralyzing if repeated often enough.

Lauder Brunton was quoted in the same paper as having stated in his "Pharmacology" that "this opposite action of large and small doses seems to be the basis of truth on which the doctrine of homeopathy was founded," following which he proceeded to criticize the fallacies of Hahnemann.

But after all, the most important point in therapeutics is to have a correct, an exact and also an early diagnosis. Thousands of persons are to-day taking hydrochloric acid and pepsin or some other exciting digestive aid for that vague entity, "stomach trouble," when the proper examination would show hyperchlorhydria or ulcer which could only be made worse by any form of acid. Nearly as many more are being dosed with alkalies when they need a contrary line of medication. Still others, suffering from a ptosis of one or more of the abdominal viscera—and their name is legion, especially among the women—are receiving various lines of treatment from drugs to osteopathy and from Christian Science to a four-weeks' fast with no possible benefit, when most of them would be relieved at once by having their displaced organs replaced and held up thereafter by either an operation, or, as I have seen in hundreds of cases, by a properly fitted abdominal supporter.

Instances could be multiplied indefinitely of failures in cases in which the diagnosis was in doubt, and yet, no consultation was had for economic or other reasons. Being no longer an aspirant for practice, I can afford to speak plainly and condemn strongly any guessing or prolonged dilly-dallying about the nature of an obscure illness whenever a consultation would probably clear up the doubt. When in such a case the patient or family refuse a consultation, the attendant would be justified in retiring from it. When, on the other hand, the family ask for a consultation and the medical attendant objects, he could have no cause for complaint if asked to make way for a broader-minded man.

Probably in no other feature is the usual current therapeutics more open to improvement than in the treatment of constipation. No affection is more common among civilized people and none is more generally treated ineffectively. The resort to purgative drugs for sluggish bowels is well-nigh universal. Patients rarely seek medical advice for the trouble early but dose themselves with laxatives till it has become chronic and aggravated. Even then, they will not often accept any curative treatment which involves time and expense, such as a course of massage, electricity or mechanical vibration (especially intra-rectal), some one of which, or a combination of them, nearly always proves effective in skillful hands, with the indispensable laxative diet and regulated exercises, often even in chronic advanced cases. Doctors should warn such patients emphatically that neither purgatives nor the milder laxatives ever cure constipation, and that, when continued very long, they may render it incurable by any method.

The diet in most chronic affections is a factor of the very greatest consequence. A more thorough study of dietetics would immensely improve the therapeutics of the average practitioner of whatever school or system.

The modern exact methods in the diagnosis and treatment of gastro-enteric affections should receive more attention in our medical colleges. If every practitioner were required to master them, or not having done so, would seek help from specialists in that line, not only in his frankly stubborn abdominal cases, but also in countless other obscure affections, he would very often be helped sooner to find the key which would solve the difficulty and obviate a harmful prolonged dependence on hypnotics or other inappropriate drugs.

While iron and arsenic will generally cure anemia after the cause has been removed, quinin and arsenic nearly always cure true malaria, and mercury and the iodids have rarely failed to rid the system in time of syphilis, to say nothing of salvarsan, it would be well if everybody, including practitioners of all sorts and the laity, could be impressed with the fact that many of the most powerful remedies are capable of doing harm in large or long-continued doses and that their safe and useful employment is often limited to the tiding over of emergencies or crises or the relief of intolerable pain, and that the cure can usually be accomplished only by a removal of the cause. In a very large proportion of chronic cases at least, the cause is some violation of health laws which demands a radical change in the patient's habits. Much of the present ineffective therapeutics results from attempts to cure people of maladies while they are continuing the bad habits which caused them.

No one can set bounds to the possibilities which may develop from the many new lines of treatment recently introduced, the antitoxins, the internal secretions from various glands, etc. The results already achieved with them afford great hopes for the future of therapeutics.

After all, however, our best and most permanent cures will not result from drugs or other special lines of treatment alone, but from supplementing these by hygienic measures, by inducing our patients to live regular and temperate lives, eating and drinking simply and never to excess, chewing all food thoroughly, taking sufficient exercise and sleep, spending as much time as possible out in the open air and sunshine and, through abundant ventilation night and day, breathing pure air whenever practicable.

South Granada Avenue.

CARCINOMA OF THE CLITORIS *

CHARLES D. LOCKWOOD, M.D.
PASADENA, CAL.

Tumors of the clitoris are of infrequent occurrence, and malignant tumors are rare. The histopathologic study of these tumors has been neglected, and many of the reported cases are not accompanied by a pathologic report. I wish to report a case.

Patient.—Mrs. K., aged 70, mother of two children, healthy, except for her present complaint. For six years she has suffered from painful micturition and irritation about the vulva. For the past year the pain on urination has been almost intolerable. She would refrain from micturition as long as possible, and then lie on her abdomen to urinate in her effort to assuage the pain. Treatment for vaginitis and irritating urine had only partially relieved her pain.

---

* Read in the Section on Obstetrics and Gynecology of the American Medical Association, at the Sixty-Second Annual Session, held at Los Angeles, June, 1911.

* Because of lack of space the review of the literature is here omitted. It is given complete in the Transactions of the Section.

Examination.—Labia minora edematous and pale. At the site of the clitoris and to the right was a small, angry-looking, oblong mass, about 2 cm. long by 0.5 cm. in breadth. This mass was ulcerated at two points and necrotic, and intensely sensitive. Urethra, vagina and uterus were normal; urine normal; no palpably enlarged glands.

Operation.—Wide excision of labia minora and tumor mass in the region of the clitoris. Tissues were dissected down to the periosteum of the pubic bone. Urethra left intact. There was free hemorrhage, requiring many ligatures. Wound closed with buried catgut and kangaroo tendon, permanent catheter in bladder.

Postoperative History.—Wound healed without suppuration, and with complete relief of symptoms. Pathologic report showed epithelioma of the clitoris. Eight months later, the patient returned with enlarged inguinal lymph-nodes. These were removed, and microscopic examination showed metostatic growth of the same histologic character as the tumor of the clitoris. After a short period of freedom from pain, the deep inguinal lymph-nodes and those lying along the deep saphenous vein became involved. The entire right leg became edematous, there was rapid emaciation, and death occurred two years after first operation. No autopsy.

The appearance of epithelioma in this region is quite characteristic. Occupying the site of the clitoris is an intensely red, angry-looking, oblong tumor. There are irregularly shaped ulcers, with indurated base, elevated above the surrounding tissues, and varying in size from a ten-cent piece to a dollar. The surfaces of these ulcers are covered either by necrotic sloughing tissue, as in my case, or by fleshy granulations which bleed easily. The borders of the ulcer are hard, elevated, uneven, and covered with granulations. The edges of the ulcer are sharply cut, rose-red in color on their inner aspect, and covered with scabs at their periphery.

ETIOLOGY

Irritation plays an important rôle in the production of cancer in this region as in other parts of the body. Among predisposing causes are, psoriasis and pruritus vulvæ, pregnancy, injuries and cicatrices of labor, irritating discharges, eczema, syphilitic ulceration and inflammatory conditions in the surrounding tissues.

CLINICAL COURSE

Epithelioma in the region of the clitoris gives rise to few symptoms and signs in the early stages. At first, there is slight burning and pain on micturition, but these symptoms are in no way characteristic, and might be due to cystitis or caruncle. As the ulceration extends, pain increases, and there is often a foul discharge with the characteristic odor of cancer. Glandular involvement is late, affording a good prognosis if removal is early and complete.

In my case, there were no palpable glands, and yet recurrence took place in eight months. Future operations for malignancy in this region should follow the rules governing the surgery of epithelioma in other regions, i. e., early and complete extirpation of the tissue involved, with all glands receiving the lymphatic drainage of the area.

Sectarianism.—"Do not give yourself up rashly and blindly to any sect. Sects are implacable despots; to accept their thraldom is to take away from one's actions and thought all liberty."—*Saying attributed to Nicon, father of Galen.*

ISOLATION OF BACILLUS TYPHOSUS FROM A WELL

D. M. LEWIS, M.D.
NEW HAVEN, CONN.

According to Chapin, typhoid fever organisms have been identified in drinking-water by the agglutination tests but four times, as quoted from Gotschlich, and since by Wesbrook from the Mississippi River, and by Fox from the Scranton reservoir.

To these six I would add another. On June 28, 1911, I received two specimens of water for analysis from a country home from which a maid had been removed to the hospital that day as a case of typhoid fever. May 11, 1911, she had been sent there to open the house for occupancy; she began to feel ill June 19, and went to bed June 24. The supply of drinking-water was from a bored, stone-laid well of approximately 20 feet depth, subject to the surface wash of the cellar floor. From April 15 until May 15 laborers were at work on the premises, cleaning the well on the former date. The maid and one other did not leave the premises at all during the period stated, and on May 16 the family of ten arrived for the season. Stored in the cellar were several barrels of cider, which later showed evidence of having been freely tapped by the laborers. There was no record of previous typhoid on the premises, or of any association of a typhoid patient or carrier with the household. The bath-room and all taps were supplied from a large storage tank filled from a distant artesian well.

The two samples of water sent in were not labeled, and while identified by me as quart milk bottles with different dealers' stamps, were identified by the sender as one with a partial crack due to sterilizing, and one not cracked. The former showed chlorin content of 1.9 gr. per gallon, absence of nitrites, less than 0.1 gr. per gallon oxygen consumed in fifteen minutes at 212 F., and a negative presumptive test for colon bacilli in lactose-bile with 10 c.c., 1 c.c. and 0.1 c.c. at seventy-six hours. Plates, lactose-bile-agar, in duplicate, showed 1,000 odd colonies after forty-eight hours, the greater proportion microscopically resembling the colon-typhoid group; morphologically a motile Gram-negative cocco-bacillus, not producing gas in dextrose or lactose media, and tested against three serums of known typhoids, gave a reaction in all three in one-half hour, dilution 1 to 100; against the dried blood of six suspects, gave the reaction (approximately 1-to-40 dilution) in but one, as was the case with the stock typhoid culture. Since, I have used it parallel to a stock culture in upward of fifty bloods, and in one case obtained a reaction from a dried blood at the seventh day, whereas the stock culture gave it only at the tenth day.

The other sample showed a chlorin content of 1.5 grains, absence of nitrites, oxygen consumed less than 0.05 and a negative presumptive colon test. Plates in duplicate showed 120 and 128 colonies, none suggestive microscopically of the colon-typhoid group.

While the first sample was identified as that from the bottle with the partial crack, and, according to the sender, as from the well, to be absolutely sure, duplicates properly labeled were sent for identification on June 30, together with a spring-water sample from a source near the lodge of the premises. The chlorin content and the oxygen consumed identified the samples, yet more surely plates revealed in duplicate the situation above stated, though somewhat less typhoid organisms in the later sample. It was quite definite that the sample that showed the typhoid bacilli was from the house well, and considering the chemical partial analysis and the negative colon test, it seemed very reasonable that urine could be the only condition giving rise to the situation.

With the vaccination of the entire household and nothing further transpiring after three months, and with the above record, I consider that I am justified in assuming the contamination of the well by some of the laborers mentioned, and that the contamination was urinary in origin.

REBREATHING IN ANESTHESIA

(Concluded from page 1599)

ABSTRACT OF DISCUSSION

ON PAPER OF DR. GATCH

Dr. Yandell Henderson, New Haven, Conn.: It seems to me dangerous to have a man breathe for any length of time through a long tube in that way. Too much stress is laid on various fixtures; there seems to be too much ventilation. We used to think we should give the patient plenty of oxygen; this apparatus is designed to keep carbon dioxid in. We already have a tube, the trachea. A man told me this morning of a case in which the trachea and blood-vessels were cut and as soon as he sewed up the trachea the man began to breathe normally. That shows that in order to keep a man breathing vigorously he must breathe through a tube, and Nature provides it. When a man breathes through his mouth he gets more ventilation than when he breathes through his nose. Carbon dioxid is a diffusible gas; if the skin is off and there is congestion and disturbed vascular conditions it is because of the absence of carbon dioxid; if carbon dioxid is put over the surface these changes do not occur. We do not draw fresh air into our lungs. It would be the simplest matter in the world for Nature to have devised a mammal as a long breathing animal in which the lungs collapsed every time; it would be a simple matter for the thorax to go down until the lungs collapsed completely; then when we took a respiration we would draw fresh air in. But it does not work that way; to a large extent it is an effort to prevent carbon dioxid from getting out rather than to get oxygen in.

Dr. J. F. Hultgen, Chicago: The case Dr. Henderson referred to came to me accidentally. There being no surgeon around, no one but interns, I had to sew up the man's trachea, which he had cut with suicidal intent. He was fainting from lack of blood when he came to the hospital. The man coughed and sputtered around on the table and so we anesthetized him through the tracheal opening. His breathing was very shallow, and I had an intern stand with a stethoscope to hear if the heart was beating (it had been suggested that we let the man alone, as he would die anyway). I put in two or three sutures on either side, not touching the cartilage, and as soon as I had these sutures in I had the intern tighten them, he holding them on one side and I doing the same on the other side, thus approximating the two ends of the trachea. As soon as we did this, the up and down movements of the chest became very extensive—more so than normal. It seemed to me this might be made use of in a great deal of thoracic work and lung surgery; that artificial tracheotomy of this sort might be advantageous. This was such a remarkable case that the nurses and those around were called to witness it. The author has brought up an interesting point about anesthesia. When I was an intern we used to give the anesthetic with a cone; we had the patient sleep for hours with this cone, pouring in a dram or two of ether at a time. The carbon dioxid theory of Dr. Gatch I think offers a good interpretation for this.

Dr. W. D. Gatch, Baltimore: I do not oppose the use of the old-fashioned etherizing cone. It can probably be used so as to meet the physiologic requirements more nearly than an open mask.

REJUVENATION OF CULTURES OF TISSUES *

ALEXIS CARREL, M.D.
NEW YORK

The duration of the life of cultures of tissues, up to now, has been very brief. In approximately from three to fifteen days after the preparation of the culture, the growth becomes progressively less rapid until it stops altogether. Following this, the tissues die and the cells disintegrate.

It may easily be supposed that senility and death of tissues are not a necessary phenomenon and that they result merely from accidental causes, such as accumulation of catabolic substances and exhaustion of the medium. The suppression, then, of these causes should bring about the rejuvenation of the arrested culture and thus increase considerably the duration of its life. As it would be important, for many reasons, to keep tissues alive outside of the organism for a long period of time, I attempted to develop a method for the rejuvenation of the cultures of tissues.

The rejuvenation consists in removing from the culture substances that inhibit growth and in giving to the tissue a new medium of development. It is accomplished by extirpating with a cataract knife the fragment of coagulated plasma containing the original piece of tissue and the surrounding new cells, which are washed for several minutes in normal or slightly hypotonic Ringer's solution.

Afterward, the fragment is placed in a hypotonic medium composed of three parts of normal plasma and two parts of distilled water. The time of rejuvenation is chosen before the appearance of the changes of senility or when they are just beginning to appear. The process described is repeated more or less frequently according to the rate of the growth and the condition of the cells.

The results of rejuvenation were studied on cultures of connective tissue. The original connective tissue was taken from the spleen, the skin, the pericardium, and the portal vein of sixteen- to twenty-day-old chick fetuses. The first rejuvenations were made when the cultures were still in the period of full growth or at the beginning of the declining period. A few hours after the passage into the new medium, elongated cells or chains of cells radiated through the plasma, and the growth went on rapidly. The washing and passage into new media were repeated when the rate of growth decreased or when large granulations appeared in the cytoplasm of the cells.

Many of the cultures were rejuvenated five, six, seven, eight and even nine times. It was observed that after the seventh or eighth passage, fusiform cells appeared in the new medium as rapidly as after the second or the third passage. Thus, the occurrence of senility in these cultures was prevented and the length of their life very much prolonged. A culture of portal vein after the ninth rejuvenation is still growing actively on the thirty-first day of its life outside of the body.

These results demonstrate that rejuvenation of the cultures of tissues is possible. They show also that, under the conditions and within the limits of the experiments, senility and death are not a necessary, but merely a contingent, phenomenon.

THE INFECTIVITY OF THE SECRETIONS AND THE DESQUAMATING SCALES OF MEASLES*

JOHN F. ANDERSON, M.D.
Director Hygienic Laboratory
AND
JOSEPH GOLDBERGER, M.D.
Passed Assistant Surgeon, U. S. P. H. and M.-H. S.
WASHINGTON, D. C.

I.—SECRETIONS

In a previous communication[1] we reported two experiments with nasal and buccal secretions from cases of measles. In the first experiment we inoculated three monkeys with secretions obtained from a patient about twenty-four hours after the first appearance of the eruption. None of these animals gave any recognizable evidence of a reaction. In the second experiment we inoculated monkeys serially with secretions obtained from a patient on each of three successive days, beginning with the appearance of the eruption. The results of these serial inoculations, checked by passage experiments, clearly demonstrated that the mixed buccal and nasal secretions in this case were certainly infective at the time of the beginning rash and again forty-eight hours later. After the publication of these results an opportunity to carry our experiments further and, if possible, to determine the duration of infectivity of the secretions, presenting itself, we made inoculations from five additional cases at various periods of the disease.

In each case the secretions were obtained by irrigating the nose and mouth with saline solution and the inoculation was made by injecting beneath the skin of the ventral aspect of the thigh. As a rule, an abscess would form within twenty-four hours and this we promptly evacuated by free incision. Healing, as a rule, was rapid.

The inoculations with their results may be briefly summarized as follows:

Case 9.—Secretions obtained three or four days after beginning of the rash; Rhesus 94 a and Rhesus 94 b inoculated (this pair of animals having given no evidence of a reaction in a previous experiment with secretions, we inoculated them from this case). Result: No evidence of reaction.

Case 10.—A. Secretions obtained about twenty-four hours after the first appearance of the rash; Rhesus 129 and Rhesus 130 were inoculated. Result: Rhesus 129 gave some indications of a reaction which, however, were not characteristic; Rhesus 130 gave doubtful indications suggestive of a mild febrile reaction.

B. Secretions were a second time collected from this case, five days after the appearance of the rash; Rhesus 133 and Java 134 inoculated. Result: Rhesus 133 presented a slight rise in temperature after six days, not sustained; Java 134 presented a slight rise in temperature sustained for three days. These may have been reactions, but it is extremely doubtful and no definite interpretation is possible.

Case 11.—A. Secretions obtained not less than six hours before beginning rash; Rhesus 131 and Rhesus 132 were inoculated. Result: Neither animal presented any recognizable reaction.

B. Secretions a second time, collected four days after beginning rash; Rhesus 137 and Bonnet 138 were inoculated. Result: Monkey 138 died of a cachexia four days after inoculation; No. 137 presented no recognizable reaction.

Case 13.—Secretions obtained three days after beginning of rash; Rhesus 139 and Rhesus 140 were inoculated. Result: Neither animal presented any recognizable reaction.

Case 18.—A. Secretions obtained when eruption was beginning; inoculated Rhesus 135 and Java 136. (These animals had previously been used with negative result in an experiment with "scales," to be described later.) Result: Rhesus 135 presented a rise in temperature which was thought to mark a beginning reaction, but passage from this animal was negative, and as it was killed by the operation of bleeding, the clinical character of the reaction could not be observed; Java 136 presented a suggestive rise in temperature, of short duration, twenty-five days after inoculation. These results, though suggestive, we consider doubtful.

B. Secretions obtained *again, four days* after beginning of rash; Rhesus 147 and Rhesus 148 were inoculated. Result: Both animals gave indications suggestive of mild reactions, but not positively interpretable.

C. Secretions collected the third time, five days after beginning of rash; Rhesus 153 and Rhesus 154 were inoculated. Result: Rhesus 154 developed peritonitis and died; Rhesus 153 presented only doubtful indications of a reaction.

It would appear then that the nasal and buccal secretions in Cases 9, 11 and 13 were not infective for the monkey and that those from Cases 10 and 18 may have been mildly infective, but a definite interpretation is not possible.

Combining the results obtained in our first two experiments with those of the five here reported and viewing them as a whole, it would appear that the nasal and buccal secretions of uncomplicated cases of measles may be at times, but are not always, infective for the monkey.

Whether this applies to the human subject is another question; but it may be of interest to recall, in this connection, that Mayr[2] failed in one of his two human experiments to infect a child with nasal mucus from a case of measles in the eruptive stage.

We may add that the seven cases from which we obtained secretions in the foregoing experiments, while all well marked, were none of them characterized by severe catarrhal symptoms. In most of them, indeed, lacrimation and coryza were comparatively slight. This may have a significant bearing in explaining the results of our experiments.

Our experiments do not permit us to draw definite conclusions as to the duration of the infectivity of the secretions, but we think that our results tend to suggest a reduction, if not total loss, of infectivity with the approach of convalescence.

II.—SCALES

The rôle of the measles scales in the transmission of the disease has long been the subject of discussion, some observers claiming that they are infective and others that the disease is incapable of being transmitted by this means. Among the latter was Mayr[3] who, using [illegible] epithelium, failed in his attempts to [illegible] with measles by this means. On account of the important practical bearing which this question has, it seemed desirable to put it to experimental test. Accordingly, we made three attempts with epidermal scales to inoculate monkeys with measles.

Experiment 1.—The "scales" in this experiment were obtained from our Case 10, five days after the appearance of the rash, by briskly rubbing the forehead, cheeks, chin, back of neck, chest and back with a swab of absorbent cotton moistened with saline solution. The liquid pressed out of this swab was divided between Rhesus 135 and Java 136, the injection being beneath the skin of the ventral aspect of the thigh, precisely as in our "secretion" experiments. The results of these inoculations we consider negative.

---

[2] Mayr, Frantz: Beobachtungen über Masern, etc., Ztschr. d. k. k. Gesellsch. d. Aerzte zu Wien., 1852, i, 13-14.

[3] Mayr, Frantz: Masern, in Virchow's Hand. der speciel. Path. u. Ther., 1860, iii, Part 3, p. 106.

Experiment 2.—In this attempt we used "scales" from four patients, namely, Nos. 14, 15, 16 and 17. These patients were in different stages of desquamation, varying from the beginning of, up to the seventh day of, convalescence. The "scales" were scraped from the face and arms of Case 14; from the forehead, neck, back and arms of Case 15, and from the forehead and temples of Cases 16 and 17, and all were mixed. With these mixed scales we inoculated two monkeys, namely, Rhesus 143 and Rhesus 144, as follows: The scales were divided into two portions; one was rubbed up in saline solution and the other allowed to remain dry. Some of the latter was introduced into the nose of each monkey by means of a glass rod and washed back with some of the saline suspension; the remaining saline suspension of scales was equally divided and injected subcutaneously. Neither monkey developed any indications of a reaction.

Experiment 3.—The scales for this experiment were obtained by scraping the face, forehead, temples, neck, arms and back of our Case 18, four days after beginning of the rash. These scales were rubbed up in saline solution and this suspension about equally divided between Rhesus 145 and Rhesus 146, the injection being beneath the skin. Neither animal gave any indications of a reaction.

The absolutely negative results of these three experiments would indicate that the "scales" employed were not infective for the monkey. Alone these experiments would hardly justify the inference that the desquamating epidermis in measles is not infective for man; but when viewed in the light of Mayr's results in children, we believe it highly probable, if not altogether certain, that the desquamating epithelium of measles, in itself, does not carry the virus of the disease.

On account of the cessation of the epidemic of measles in the city of Washington we have been obliged to bring our work temporarily to a close. The work which we here record and that which we have previously reported[4] in brief, we hope to publish in detail in a bulletin of the Hygienic Laboratory.

We desire again to express our grateful appreciation to our many friends who have aided us with cases of measles and to our colleagues at the laboratory and at Ellis Island for valuable assistance in the experiments.

Concentration of Energy.—Sir William Ramsay, in his presidential address before the British Association, says that "the whole progress of the human race has indeed been due to individual members discovering means of concentrating energy, and of transforming one form into another. The carnivorous animals strike with their paws and crush with their teeth; the first man who aided his arm with a stick in striking a blow discovered how to concentrate his small supply of kinetic energy; the first man who used a spear found that its sharp point in motion represented a still more concentrated form; the arrow was a further advance, for the spear was then propelled by mechanical means; the bolt of the crossbow, the bullet shot forth by compressed hot gas, first derived from black powder, later, from high explosives; all these represent progress. To take another sequence: the preparation of oxygen by Priestley applied energy to oxid of mercury in the form of heat: Davy improved on this when he concentrated electrical energy into the tip of a thin wire by aid of a powerful battery and isloated potassium and sodium."

PHENOL (CARBOLIC ACID) GANGRENE

EVERETT J. BROWN, M.D.
DECATUR, ILL.

Although many cases of gangrene from the use of phenol have been reported in recent years, they were mostly the result of the application of wet phenol dressings to the fingers or toes. In the case which I report here, the gangrene was due to the use of phenolized petrolatum in treating a bruised finger-end. The ring finger was affected. The mother stated that the physician had extemporaneously mixed the petrolatum and phenol; hence the strength was unknown. It did not whiten the finger, however, and the gangrene did not develop for several days. The finger was completely black and not painful except at the line of demarcation. Amputation of the whole finger was required. The boy was 5 years of age.

The cases reported by Harrington several years ago were mostly due to the use of phenol solutions in varying strengths applied as wet dressings to the fingers, but the above case emphasizes his warning of the danger of using phenol in any form as a dressing for fingers or toes.

SODIUM PERBORATE AS A DRESSING IN THE TREATMENT OF DIABETIC GANGRENE

A. HERZFELD, M.D.
NEW YORK

I have, in the past three years, extensively used sodium perborate and published a short article[1] on the treatment of epistaxis with this drug in 1909, in which the method of its use was exactly described. Further, I have used it successfully, not only in epistaxis, but also in secondary hemorrhage after adenoid operations and tonsillotomies.

I have used sodium perborate frequently in infected wounds, in acute and chronic ulcers, and in three cases of diabetic gangrene, in which the results were so marked, that I wish to report these cases.

CASE REPORTS

Case 1.—L. W., aged 48, up to two years previous enjoyed good health, had a family history of diabetes. For the previous two years he had been suffering from diabetes. In September, 1909, the patient had a phlegmon of the large toe of the left foot, which reached to the metatarsus. This was operated on. During the healing of this infection the third toe on the same foot began to become gangrenous; in a few days a line of demarcation formed; the patient refused amputation. The dead tissue was removed with the scissors, a dry sodium bicarbonate dressing had been used, but seemed to have no influence on the process. From October 15 sodium perborate was used by daily covering the whole surface with the dry powder (in the beginning twice daily). The wound rapidly developed healthy granulations, and Jan. 15, 1910, the patient was discharged completely cured. The sugar percentage varied from 1 to 3. Acetone was present. The patient died six months later of a complicating nephritis.

Case 2.—V. C., aged 42, female, colored, up to four years previously was in good health; since that time she complained of severe pains in muscles and joints, probably of rheumatic origin. Examination Oct. 5, 1909, revealed a large abdominal tumor (myoma) extending to the umbilicus, a loud systolic murmur over the mitral valve with hypertrophy (mitral regurgitation). On the inner surface of the left thigh was an ulcer of the size of a silver dollar, edges black and gangrenous, with flabby granulations. The patient stated that she had, fifteen years prior, a "sore" on the vulva. This ulcer on the thigh was treated as of luetic origin. The result was deterioration in the patient's condition and no improvement whatsoever in the ulcer. The urine was examined Nov. 2, 1909, and showed sugar but no acetone. The ulcer was now dressed with dry sodium perborate powder. It began to heal and was completely healed by Dec. 26, 1909.

---

[1] The Journal A. M. A., March 13, 1909, p. 890.

Case 3.—S. H., aged 54, had a family history of diabetes; one brother died of Raynaud's disease. The patient, during a severe attack of pneumonia after an influenza, had numerous injections of camphor in oil (1 camphor to 4 sterilized olive oil) given, which injections caused six gangrenous ulcers on the thigh. Three of these coalesced and made an ulcer 3 inches in length and 1½ inches in width, and when the gangrenous material was removed was ½ inch deep. The wound was dressed twice daily for six weeks, Jan. 17 to March 3, 1911, with sodium perborate in powder form and slowly but steadily healed completely. The patient during this time had 1 per cent. of sugar but no acetone.

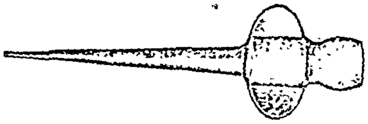
All of these patients were placed on appropriate diet and general treatment for diabetes.

224 West Twenty-Fourth Street.

URETERAL CATHETER COUPLER

BURTON HARRIS, M.D.
BROOKLYN

Hypodermic needles, soft rubber connections and various other makeshift devices hitherto employed in coupling a syringe to a ureteral catheter, are unsatisfactory because they permit leakage. A conical needle made after my suggestions obviates this difficulty.



Ureteral catheter coupler.

The instrument here illustrated is 3.17 cm. in length, measuring 13 French at the base, and the tip is sufficiently small to be readily introduced into the lumen of a 5 French catheter. It was designed to fit the Ehrlich-Hata Record syringe, for the reason that the latter is of convenient size and has the obvious advantage of a screw connection. However, it may be attached to the Janet-Frank or other syringe by means of a section of soft rubber tubing.

475 Greene Avenue.

New and Nonofficial Remedies

The following additional article has been accepted by the Council on Pharmacy and Chemistry of the American Medical Association. Its acceptance has been based largely on evidence supplied by the manufacturer or his agent and in part on investigation made by or under the direction of the Council. Criticisms and corrections are asked for to aid in the revision of the matter before publication in the book "New and Nonofficial Remedies."

The Council desires physicians to understand that the acceptance of an article does not necessarily mean a recommendation, but that, so far as known, it complies with the rules adopted by the Council.

W. A. Puckner, Secretary.

BISMON.—Colloidal Bismuth Oxide.—Bismon is claimed to be a preparation of colloidal bismuth meta-hydroxide containing about 20 per cent. metallic bismuth.

It is stated that Bismon results from the action of sodium lysalbinate and sodium protalbinate on bismuth salts.

Bismon is a light brown granular substance, forming with water, a fairly stable opalescent colloidal suspension (in these suspensions colloidal bodies are in such extreme state of subdivision that they were formerly supposed to be in solution and are still commonly so considered). In aqueous suspensions, decomposition manifested by the appearance of a black deposit is said to set in after three to four weeks. The aqueous suspension is not affected by metals.

If an aqueous solution of egg albumin be added drop by drop to a 1 per cent. aqueous suspension of bismon a white precipitate forms, soluble in an excess of the albumin solution.

If hydrochloric acid be added to an aqueous suspension of bismon a white turbidity soluble in an excess of the acid appears.

If hydrogen sulphide be passed into a 1 per cent. suspension of bismon a dark brown color, but no precipitate is formed. The addition of acid to this suspension produces a brown precipitate.

Bismon, when heated, chars, with evolution of fumes of burning nitrogenous matter, yielding finally a residue, which when dissolved in nitric acid responds to tests of identity for bismuth.

If 1 gm. bismon be gradually heated with fusion mixture, until all carbonaceous matter has been destroyed, the fused mass when cooled, dissolved in nitric acid, the bismuth precipitated with ammonium carbonate solution, the resulting precipitate when ignited to constant weight should yield at least 0.2198 gm. bismuth oxide (Bi_2O_3) corresponding to 19.7 per cent. bismuth.

Actions and Uses.—Bismon has the actions of other preparations of bismuth, but it is claimed that, on account of its solubility (property of forming colloidal suspension) it is more rapidly distributed over the mucous membrane of the gastro-intestinal tract.

It is said to be useful in acute and chronic intestinal derangements and in various forms of dyspepsia in infants and young children.

Dosage.—0.5 Gm. (7½ grains) in 5 to 10 per cent. solution (colloidal suspension) in water. The solution (colloidal suspension) may be added to milk or other appropriate liquid food.

Manufactured by Kalle & Co., A. G., Biebrich on the Rhine, Germany. (Kalle & Co., Inc., New York.) Trademarked in Germany. Not patented or trademarked in U. S.

Therapeutics

ANESTHESIA AND ANESTHETICS

(*Continued from page 1539*)

ADMINISTRATION OF ETHER

A very common method of the administration of ether has been by means of a cone made of paper and lined with a towel or napkin, with perhaps the addition of a sponge or some absorbent cotton. The ether in small amount is poured into the cone, and it is then placed over the nose and mouth of the patient. As the ether evaporates from the towel or other absorbent, fresh ether is of course added.

This method has some serious objections, the most important of which is that the strength of the ether vapor inhalations, i. e., the percentage of ether vapor contained in the air inhaled, is extremely variable. In practice it is generally attempted to counteract this variability by not holding the cone close to the face of the patient immediately after the ether has been poured into it, but even this does not allow of an accurate administration or of an administration continuously of one even strength of the vapor.

Various forms of apparatus have been devised to counteract these objections and to enable the ether to be administered continuously of a uniform strength. While these methods of administration are practicable in a large hospital where a physician is always at hand who is familiar with their use, in general practice and in the hands of men who do not frequently administer an anesthetic, and therefore are not especially skilful, it is desirable to find a simple method which will be at the same time efficient and safe.

A method of administering ether in continuous, regular quantity has been called the dosimetric method, which consists essentially of allowing the ether to fall, drop by drop, on a piece of thin fabric, such as flannel, which is supported on a wire mask like the well-known Esmarch chloroform mask. One of the originators of this method is Allis, of Philadelphia, who presented to the profession, in 1874, the so-called Allis inhaler, which consists of a large number of layers of flannel supported on a metallic frame, the whole surrounded by a cuff of rubber (in the best examples) which is open at both ends. Of the different inaccurate methods of administering ether, perhaps this is as good as any. The ether is dropped on the flannel through the top of the inhaler, and the drops should be well distributed over the flannel. This allows a considerable admixture of air, so that the patient does not suffer from lack of oxygen. At present, however, many prefer the wire mask covered with a single layer of flannel.

One great objection to these inhalers is that the rapid evaporation of the ether greatly chills the air which is taken into the lungs, and this may predispose to a post-anesthetic pneumonia.

The administration of ether is often attended by more or less discomfort. Early in the inhalation there is produced considerable irritation of the respiratory passages, so that the patient has a choking sensation and feels an irresistible desire to cough. This is probably due in most instances to the ether being administered too concentrated. If the ether is given in a very small quantity at first and then gradually increased in concentration, these unpleasant sensations may generally be avoided without any particular increase in the total time required to produce complete anesthesia. It is absolutely unjustifiable to push the anesthetic so that the patient has a closure of the glottis and a sensation of suffocation. Such an administration of ether is the cause of the spasmodic contractions of the muscles and the fighting of the patient for air. It is as sensible as would be deliberate choking of the patient. If an insane patient or a young child fights an anesthetic, ether should not be used until the patient has been anesthetized by chloroform or by nitrous oxid gas.

As the patient approaches complete anesthesia considerable annoyance is often caused by the dropping back of the tongue and the consequent interference with respiration. This may generally be avoided by placing the ends of the fingers of each hand back of the angle of the jaw and lifting it forward, or by lowering the head and extending the neck, with chin high. In some cases it may be necessary to seize the tongue with a pair of forceps and draw it forcibly forward. If the head is turned to the side, the tongue is less likely to fall backward.

A very unpleasant feature of the administration of ether in many patients is the stimulation of the muciparous glands of the mouth and throat, so that the throat becomes filled with mucus, which causes gurgling, nausea, and even choking. It often requires frequent swabbing of the mouth and throat with gauze, or better with pieces of sponge, grasped in a pair of long forceps. Such a profuse secretion is sometimes avoided by the hypodermatic administration of atropin (1/150 to 1/100 of a grain), from half an hour to an hour before the administration of the anesthetic.

It has been suggested to inhibit this profuse secretion by means of epinephrin solutions. Such solutions have been sprayed into the throat, or it has been suggested that a few drops of a weak solution (perhaps 1 to 10,000) be placed in the inhaler along with the ether, once in five or ten minutes. If the epinephrin solution is sprayed into the throat directly, and probably if it is carried in with the ether vapor, contraction of the arterioles of the throat will certainly occur. The exact amount of epinephrin that will actually be absorbed in this manner is of course problematical. It should not, however, be used carelessly, as it has long been demonstrated that epinephrin is, if introduced into the blood in any considerable quantity, depressant to the respiratory center, which of course would be very undesirable in ether narcosis.

The rapid method of administering ether, termed the "ether rausch," which has been used much in some clinics in Germany, and is mentioned by Dr. William T. Coughlin (THE JOURNAL, July 1, 1911, p. 17), is perhaps occasionally useful, but seems generally hardly justifiable. The patient breathes, for a portion of a minute, pure ether undiluted with any gas or air. Anesthesia is almost immediately temporarily complete, and minor cutting can be done, the anesthesia lasting from three to five minutes. There seem to be rarely after-effects like nausea and vomiting. On the other hand, theoretically it does not seem very safe.

For method of administering ether by means of a tube passed through the nostrils, and by the rectum, see THE JOURNAL, July 30, 1910, page 402.

Ether has been given intravenously by mixing it with cold water and then heating over a water bath so that the excess of ether evaporates, leaving a 4.68 per cent. solution. From 1,000 to 3,000 c.c. of such a solution have been infused into the blood-stream without any untoward symptoms (*München. med. Wchnschr.*, July 11, 1911). This method has been used in the surgical clinics at Greifswald. It would seem that such a method of administering ether would be very rarely justifiable.

Before commencing the administration of the anesthetic, the anesthetist should give careful attention (1), to the operating-room; (2), to the emergency table; (3), to the patient.

The *operating-room* must be warm, and the operating-table as comfortable as possible for the patient. There must be plenty of blankets. The legs and arms, a low pillow for the patient's head, and a pillow for the back, should all be arranged to be as comfortable and warm as possible without, of course, interfering with the exigencies of the particular operation. It is advisable to have a strong, well-working faradic battery, an oxygen tank (it should be remembered that Professor Henderson thinks too much oxygen in ether shock is inadvisable, and even advises carbon dioxid gas), transfusion apparatus, and warm, aseptic physiologic saline solution.

The articles on the *emergency table* should comprise:

1. Chloroform.
2. Ether.
3. Petrolatum.
4. Boric acid eye-drops (1 per cent.)
5. Tongue forceps.
6. Long forceps for swabbing, and properly made gauze or cotton pledgets (no ravelings), or pieces of sponge.
7. A mouth-gag, or cork, or a piece of rubber.
8. A large needle threaded with strong silk.
9. A pus basin.
10. Towels.
11. Two hypodermic syringes.
12. Atropin sulphate tablets (each 1/200 of a grain). (The amount is small, that the dose may be repeated, if needed.)
13. Strychnin sulphate tablets (each 1/40 of a grain). (The amount is small, that the dose may be repeated, if needed.)
14. Ampoules of saturated solution of camphor in sterile olive oil.

15. Ampoules of aseptic ergot.
16. Epinephrin solution in aseptic ampoules, 1-10,000.

The Patient:

1. A twenty-four hours' specimen of urine should, if possible, have been examined; certainly a single specimen should have been examined.
2. The condition of the heart and arteries should have been examined and the best anesthetic selected.
3. The patient should have received no solid food for a number of hours before the operation. If the operation is done early in the morning, it is best, three hours before the operation, to give either a cup of hot bouillon or a cup of black coffee.
4. The bowels should have been properly moved, generally by the aid of some cathartic, and often an enema is advisable at least an hour before the operation.
5. The urine should have been passed immediately before the administration of ether is begun.
6. False teeth should be removed. The nose, throat, mouth and teeth should be cleansed with an antiseptic wash. Hairpins should be removed, if the patient is a female, and the hair should be properly bound up under a cap; it is better that this cap is not made of rubber, as the head is likely to become very moist with perspiration, if the cap is impervious.
7. The face should be anointed with petrolatum, as the vapor of ether is irritant to the skin.
8. The rate of the pulse and the feel of the radial and temporal arteries should be noted before the anesthetic is begun.

The anesthetist should be a physician who has been especially trained for this work. He should give his entire attention to the anesthesia, and his attention should not be diverted from his own work to watch the operation, or for any other purpose. He should keep himself aware of the condition of the heart by holding the index-finger of one hand over the temporal artery where it passes over the zygomatic process in front of the ear. He can be aware of the condition of the respiration either by the rise and fall of the chest, or by feeling the exhalation of the air through the mask.

Next to the pulse and respiration, the pupil is the most important index to the condition of the patient. Sudden dilatation of the pupil, especially if accompanied by hiccough, are grave symptoms, and should lead to the immediate suspension of the anesthesia and the withdrawal of the ether.

In order to determine when anesthesia is complete, many separate the eyelids and touch the conjunctiva with the tip of the finger. This is a dangerous practice, and should not be followed, as the eye may be injured or infected.

The most useful test for determining complete anesthesia is raising the arm. If this falls without any muscular contraction, the anesthesia is complete. This condition may be present shortly after the administration of the ether is commenced, the so-called primary anesthesia, which may be followed by a brief return of muscular activity. The continued administration of the ether will soon produce complete anesthesia. If the operation is an abdominal one, a little ether poured on the abdomen will soon show, by reflex action from the cold, whether the patient is thoroughly anesthetized or not. Also, manipulations of any kind at the region to be operated on will often awaken an incompletely anesthetized patient when other signs have apparently pointed to complete anesthesia.

The patient should be kept as lightly under the influence of the anesthetic as is possible. Very deep anesthesia should be avoided. The anesthesia should be as brief as possible, but this, of course, rests with the operator. As soon as an operation is completed, the ether should be withdrawn. Often this can be done before the final stitches are inserted and the dressing applied. If the patient has not been too deeply anesthetized, he should begin to regain consciousness shortly after the withdrawal of the ether.

One of the most troublesome of the sequelæ of the administration of ether is nausea and vomiting. The exact cause of this has not been determined definitely. Some have believed that it was due to the irritation of the mucous membrane of the stomach from the ether swallowed, but this is probably not so, at least in all cases. Various methods have been proposed to combat this disagreeable symptom. All are more or less successful. If morphin has been administered before the operation, nausea does not occur as soon as when it has not been administered. It is often advisable to give an injection of morphin and atropin directly after the patient comes out of the anesthesia, that he may not suffer pain and shock from such pain. Such an injection prevents the nausea, at least for a number of hours. Hot water, administered frequently in teaspoonful doses, is often a successful, simple treatment. If mucus and gas are eructated, or actually vomited, large draughts of hot water should be taken, that the stomach may be thoroughly washed out by vomiting, or by the liquid passing the irritant onward into the bowel. Some surgeons believe in washing out the stomach. This is not often advisable, but is indicated if bile is regurgitated, or if blood is extravasated into the stomach. Oxygen inhalations have been suggested (The Journal, April 27, 1907, p. 1421). Pure olive oil, in ounce doses, has also been found useful in this condition (The Journal, Dec. 18, 1909, p. 2094). Of course, the oil would soothe the stomach, and would be especially sedative, if there was increased secretion of hydrochloric acid, which secretion oil inhibits.

As soon as possible after anesthesia, a starchy food, as oatmeal, should be given to prevent a possible development of an acidosis.

A not infrequent sequence of the administration of ether is an irritable bladder and more or less kidney congestion. This is shown by a slight albuminuria and by a diminished amount of urine. Such an irritation may be caused not only by the ether itself, but also by the profuse sweating and the small amount of liquid which has been ingested, causing the urine to become very concentrated and therefore irritant. To prevent such irritation, it is often good treatment, after an operation, to inject a pint of hot water, with or without salt (a physiologic saline solution), into the colon. Such liquid is rapidly absorbed and dilutes the blood and all the secretions and increases the excretion of urine. Such frequent irritation of the kidney renders it inadvisable, unless there is positive necessity, to administer ether a second time to the same patient within so short a period as a week. In fact, it has been shown that serious kidney congestion can occur following an ether or chloroform narcosis several weeks subsequent to the anesthesia. The fact of this tendency to irritate the kidneys makes ether as an anesthetic generally contra-indicated when there is kidney disturbance, especially if there is any acute inflammation present.

Dr. P. B. Hawk (*Arch. Int. Med.*, Aug. 15, 1911, p. 177) has shown that after ether anesthesia the urine excretion function of the kidneys is diminished. This of course has been clinically long recognized, and has been attributed to the greatly diminished amount of water ingested for a number of hours and to the profuse sweating caused during anesthesia. Hawk has seemed to show that there is actual diminished activity of the kidneys, perhaps from depressed circulation. Normally, the kidneys in a few hours after the anesthesia is ended, begin to act efficiently, especially if a physiologic saline solution is placed in the colon.

To hasten the elimination of ether from the system, plenty of fresh air should be allowed in the room, provided it is sufficiently warm. The patient, under any circumstances, must be surrounded with hot-water bottles and blankets so that he may not lose too much heat, or better, may even acquire heat, during the shocked condition subsequent to anesthesia, such a condition being generally present. Such care that the patient does not lose heat is an important preventive of surgical shock.

If much blood has been lost and the patient is in a condition of collapse, besides administering physiologic saline solution by the rectum, intravenous or subcutaneous transfusions of saline solutions are often advisable. Raising the foot of the bed should also not be forgotten in this condition. It may be here parenthetically stated that when the Trendelenburg position has been long used in an operation the return of the patient to a level should be brought about gradually, lest anemia of the brain be caused.

When a patient has lost a large amount of blood, or there is a condition of shock already present, or it is feared that the patient is not going to stand the operation well and yet the operation must be done, the blood from one or both legs has been shut off by tourniquets. When the circulation entirely ceases in the extremity so treated, the blood there contained is, of course, free from the anesthetic, and may be turned in to the general circulation at such time as the anesthetist or the operator decides. The patient will of course be revived by such blood. Perhaps the extremity and its blood should not be shut off from the general circulation more than half an hour lest some trophic or nerve changes occur. Danger from clotting and therefore from emboli might well be considered, if there are diseased arteries. High blood-pressure and cerebral congestions may contra-indicate this procedure.

Another untoward effect is sometimes observed in the supervention of an attack of pneumonia. It has been proved that either ether, chloroform, or alcohol diminish the resistance of the cells to bacteria. Pneumonia is more apt to supervene when the narcosis has been deep and protracted. Many believe that it is also encouraged by the inhalation of cold air with the ether, and it also undoubtedly happens that the development of pneumonia is promoted by the exposure of the patient, while under the influence of the anesthetic, by allowing the coverings to slip off from his body and limbs, or from allowing him to lie in coverings or clothing saturated with blood or other fluids used during the operation. It is exceedingly important that a patient under an anesthetic should be kept warm and dry. Various devices have been designed for keeping the patient warm by appliances connected with the operating table. These are often useful, but caution should be exercised lest the patient, while unconscious, should be burned by such appliances.

As just stated, pulmonary congestion and postoperative pneumonia are frequent serious occurrences after prolonged anesthesia, especially after prolonged etherization. Various factors have been assigned an influence in the etiology of these pulmonary conditions. Among others, it has been alleged that probably the chilling of the respiratory organs by the evaporation of the anesthetic has an important part. It has been observed that anesthetics seemed to act better in warm climates and in warm weather. From these observations it has been deduced that if the anesthetic is warmed before it is administered, there will be less danger of pulmonary sequelæ. During the last ten or fifteen years many anesthetists have insisted on having the anesthetic itself, or the vapor, warmed before it is inhaled by the patient. This may be accomplished in various ways. For ordinary use, the warming of the can of ether or the bottle of chloroform to about the temperature of the body would seem to be most desirable. The inhalation of an anesthetic at this temperature results in less irritation in the throat at the beginning of anesthesia, the early accession of complete anesthesia, the necessity for a smaller amount of the anesthetic during the operation, and hence fewer after effects.

Many patients complain of backache after an operation. This is probably due in many cases to straining of the muscles of the back on account of the back not being properly supported while the patient is unconscious. In order to avoid this a small pillow should always be placed under the lumbar region of the patient while he is on the operating table.

The question frequently arises whether to anesthetize the patient in the operating-room and on the operating table, or in an adjoining room. With reference to this it should be urged that the less a patient is moved about after the administration of the anesthetic is commenced, the better. On the other hand, a nervous patient should generally be anesthetized in an adjoining room, and if possible, on a stretcher or rolling table, so that he may be transferred to the operating-room and then to the operating table with the least possible general disturbance.

As elsewhere stated, the ability to withstand infection is greatly reduced after an etherization. How long this susceptibility to infection persists it is difficult to determine, as it probably varies in different individuals. It seems that the opsonins of the blood and the ability of the polymorphonuclear cells to increase in number and act as phagocytes are certainly diminished. It has been shown by Graham (*Jour. Infect. Dis.*, 1910, viii, 147, and The Journal, March 26, 1910, p. 1043), that when lecithin is added to blood whose ability to fight disease is thus diminished, it rapidly brings its resistance to infection up to normal. Olive oil given by the rectum is also shown to increase the opsonic power of the blood. When it is remembered that ether and chloroform have been shown to combine with fat elements and certainly with lecithin, the administration of a lecithin preparation or the administration of rectal injections of olive oil seems scientifically good treatment after etherization.

CONTRA-INDICATIONS OF ETHER

Ether is contra-indicated if there is present disease either of the lungs or kidneys. Other contra-indications to the use of ether are chronic alcoholism, aneurysm, very high blood-pressure, and an atheromatous condition of the arteries.

CAN HAIR TURN WHITE IN A NIGHT?

A cherished popular belief is that of the sudden blanching of the hair from fright, worry or other severe mental strain. It plays its part in the drama and in fiction, while history records its famous instances. Who has not heard that Marie Antoinette's hair turned white during the night before her execution, or that the deeds and terrors of St. Bartholomew's night blanched the hair of Henry the Fourth? Most of us have wondered how the change could come about so rapidly as tradition relates; and yet so universal is the belief in this phenomenon that few have the hardihood to doubt it. One may accept one theory, that a sudden entrance of air or gas into the hairs makes them gray or white; or one may accept Metchnikoff's idea that it is all done by hungry, pigment-loving phagocytes, or one may take the stand of Stieda and boldly say that it isn't so at all. This refractory German first proves that such a thing couldn't possibly happen, and then, not satisfied, declares that it never did happen. With equal disregard of folk-lore, history and medical literature, he points the finger of doubt, and challenges many long-deceased historians and physicians to arise and prove their stories.[1]

In an extensive article[2] he shows that when the hair turns white under ordinary conditions it does so in one of two ways. Either the pigmented hairs fall out and are replaced by unpigmented hairs, or, less commonly, pigment-production stops in a growing hair and the colorless portion gradually replaces the darker outer segment. In neither case is there a bleaching or removal of existing pigment from the hair, leaving it colorless. Metchnikoff's theory of removal of pigment by phagocytes, and the older hypothesis of bleaching of the hair by formation of gas bubbles, are both, Stieda believes, entirely incorrect.

As this work supports the theory that hair becomes white only by replacement, and as the growing of a new crop of hair in a single night is beyond the possibilities of even the Seven Sutherland Sisters, the author must needs discredit all tales of such miraculous transformation. This he does *in extenso,* taking up the best-known instances of such supposed blanching of hair, and finding them all lacking in support sufficient to meet critical consideration, much less such control as to establish an acceptable scientific demonstration. For example, he finds that Charcot doubted the story of Marie Antoinette's sudden loss of hair pigment, stating that although the queen certainly was gray at the time of her execution, yet this was no novelty, for she was also gray nine months before, at the time the king met his sudden end at the hands of the revolutionists.

As for the rest of the reputed cases, many are nothing better than old-wives' tales, while others are examples of medical credulity substituted for healthy skepticism and careful investigation. The explanation for many is unkind, being simply that the keeper of the jail or dungeon in which the unhappy heroine or hero was confined neglected to furnish his guest's dressing-table with the hair-dye to which the latter had been accustomed at home, and that Nature asserted herself before release or execution. Verily the iconoclast respects nothing—not even the gray hairs of royalty.

MILK-BORNE TONSILLITIS

Epidemics of "septic sore throat" in England have from time to time been attributed to milk-supply, but in this country such outbreaks seem to have been less common, or, at all events, less commonly recognized. The fact that the remarkable epidemic of virulent tonsillitis occurring in Boston and vicinity last spring has been carefully investigated is therefore matter for congratulation. The Boston epidemic, including the cases in Brookline and Cambridge, affected over one thousand persons, forty-eight of whom died. There is now presented unimpeachable evidence showing that the epidemic was spread in milk from the Southboro farm of the Deerfoot Company, the infection of the milk apparently originating in an epidemic of the same character which prevailed in Southboro and neighboring towns during some six weeks preceding the Boston outbreak.

Apart from the high degree of virulence apparently possessed by the streptococcus strain concerned in the epidemic, there are other features of special interest. The milk-supply implicated has been for some years one of the most favorably regarded among the large Boston supplies. This was due not only to the facts that excellent regulations were in force to avoid contagion and that cattle and farms were carefully inspected, but also to the fact that the whole process was controlled by an experienced and well-known laboratory worker under contract with the Deerfoot Company. The recent searching inquiry has failed to reveal any instance of neglect or lack of precaution. In a word, the conditions surrounding the implicated milk-supply would be considered ideal and to-day are so considered by the best authorities on dairy sanitation. Here infection leaped the barriers of all known precautions. "Boston has suffered severe lessons along this line. In 1907 there

2. Anatomische Hefte, 1910, xl, 285.

were 717 cases of scarlet fever traced to one milk-supply, and seventy-two cases of diphtheria to another. In 1908 there was a milk-borne outbreak of typhoid fever totaling 400 cases. In 1910 there was another scarlet fever epidemic of 842 cases. Including the present outbreak, there have been over 3,000 cases of epidemic disease traced to milk in the immediate neighborhood of Boston in a period of five years."[1]

The Boston epidemic seems to cast some doubt on the value of the method of controlling the public milk-supply by inspection rather than by pasteurization, but cannot be regarded as wholly condemning efficient inspection, as inspection raises the general standard of cleanliness and consequent safety of milk. Accidental contamination under almost ideal conditions is always a possibility. Our readers will be reminded of the recent epidemic of diphtheria among the students and faculty of the University of Minnesota on which we have commented.[2] In this case the source of infection was one of the cleanest and best-regulated dairies in the Minneapolis district, the contamination coming from a human source. The Boston epidemic demonstrates again that milk from a "model" farm may, through accidental contamination, spread contagion widely. In this latter case there was no evidence that diseased cattle were the source of infection, the facts discovered in the investigation rather strengthening the hypothesis of a human origin. Probably a temporary "carrier" was concerned. Inspection is an expensive process and many sanitarians have pointed out that in the nature of things it cannot afford absolute security, a statement that seems to be confirmed by the instances mentioned. With no desire to advocate or approve of the abandonment of careful inspection of dairies, notwithstanding its expensiveness, we must admit that the results of investigation of these two epidemics tend to support the advocates of general pasteurization of public milk-supplies.

UNDERNOURISHMENT AND GROWTH

The interrelation of malnutrition and growth is a topic of preeminent interest in practical pediatrics as well as in physiology. The expression "retarded development" is ordinarily applied to a failure to gain in body weight. There are obviously two simple clinical methods of measuring growth, namely, by body weight and body length. But both of these factors which afford the external expression of internal developmental changes are not necessarily halted at the same time. Indeed, it has frequently been noted that poorly nourished atrophic infants may continue to grow in size to a considerable degree.[3]

At first glance it may seem somewhat anomalous that an individual should exhibit growth in the absence of any increase in body weight. Quite recently several experimental contributions have thrown a new light on this question. H. Aron,[4] some of whose interesting studies on nutrition in the Philippine Medical School have already received notice in THE JOURNAL, has made careful measurements on dogs to ascertain whether or not it is possible to suppress the process of growth entirely by restriction of food, and if so, for how long. Among a number of comparable animals in each series, some received just enough food to keep their body weight constant; others, varying additional amounts, so that more or less intensive growth resulted. The striking outcome was that if a growing dog is kept at a constant weight, or even at a slightly decreasing weight, the bones continue to increase in weight and therefore to grow, although not quite so rapidly as in a normally fed control animal. If the bones have absolutely and relatively increased in weight, while the total weight of the animal has been kept constant, it is obvious that other parts of the body must have lost in weight.

The glandular organs are apparently not seriously involved in this process of consumption. The analyses indicated that the tissues which have undergone loss during the underfeeding are the muscles and fat. Of peculiar interest is the observation that the brain has nearly the same weight in a growing dog kept at constant weight as in a normally developed animal. This reminds one of the condition in so-called infantilism, in which children may exhibit a marked mental development despite the retardation of growth in its more obvious aspects. The losses in Aron's dogs, aside from the fat, involve a quantity of protein especially from the muscles, while a great proportion of the body tissue, notably in the blood, is replaced by water. The latter, with the increase in the skeleton, replaces the body materials lost.

A point of practical interest lies in the fact, here experimentally demonstrated, that during the period of growth a stationary condition in respect to body weight may actually be the expression of starvation. Only in the last stage of emaciation, when there are no body reserves to draw on, is growth entirely suppressed.

Similar observations have been made by Waters[5] on growing cattle. This author says that ungrown animals that had been previously well nourished continued to increase in height and in width of hip for a considerable length of time, even though on a starving ration. Apparently, the animal organism is capable of drawing on its reserve for the purposes of sustaining the growth process for a considerable time and to a considerable extent. His experiments indicate that after the reserve is drawn on to a certain extent to support growth, the process ceases and there is no further increase in height or in length of bone. From this point on, the animal's chief business seems to be to sustain life.

[5] Waters: The Influence of Nutrition on Animal Form, Bienn. Rep., Kansas State Board of Agric., 1911, xxii, 199.

Few comparable measurements have been made on undernourished children. Data published by Freund[4] point, however, to similar phenomena in human development, where some growth in length is not checked by underfeeding.

From the foregoing it appears as if "the tendency to grow in a young animal is greater than the tendency to maintain life" (Aron). The tendency to grow is possessed principally by the skeleton, which sets the pace for the other tissues to follow if possible. It is highly significant to find that the capacity to grow is not necessarily lost through early malnutrition. Re-alimentation and renewed growth follow more or less normal courses, so that, as the recent measurements by Birk[5] on children show, earlier losses may be regained.

The facts reviewed are of importance in practical pediatrics. Aron says: "A child which does not increase in weight or increases slowly is so undernourished that part of its own body substances are being consumed. We can go even further in our conclusions. If a child does not present the weight which we have a right to expect at its age, assuming that it was born with a more or less normal weight, this child's body does not have the normal composition. It will contain a higher percentage of bones, a lower content of fat and muscle tissues, and a higher content of water." To feed such children properly is fundamental.

PREVENTION AND NOT TREATMENT

An osteopathic association recently adopted a resolution favoring a national department of sanitation, but opposing a national department of medicine. This is encouraging, and this osteopathic association is to be congratulated on its broad-mindedness and perspicacity. We did not know, however, that anyone favored a department of medicine, or that there had been a suggestion that one be established. The Journal has again and again insisted that the sectarian adherents were exciting themselves unduly and needlessly. A national department of health would be charged with the work of studying the cause and methods of preventing diseases. It would have nothing to do with the treatment of individual patients or with the practice of individual physicians. Those who object to the Owen bill on such grounds are incapable of distinguishing between the scientific study of disease in the abstract and the care of the patient suffering from the disease. The first is an important public duty. The second is a matter of personal choice. The vague and awful charges of "establishing a state school of medicine," "medical tyranny," "perpetuation of a medical trust," "interference with personal liberty," etc., are made either through ignorance or through a desire to mislead the public as to the real purpose of such a measure.

Let it be repeated again: Congress has no power to pass any law interfering with the practice of medicine in the states. Neither Congress nor any state legislature has any right to compel any sane adult to take any form of treatment against his will. The Owen bill does not create a single new bureau or division. It simply collects, in a single department, certain existing bureaus and divisions having functions bearing on public health. It authorizes the establishment of laboratories and the employment of scientific experts to study disease as Koch studied tuberculosis, as Carroll and Lazear and Agramonte studied yellow fever, as Stiles and Ashford studied hookworm, as Ricketts studied mountain fever, as Flexner is studying cerebrospinal meningitis.

Have any of these men interfered with personal liberty? Has not the victory over yellow fever, as the result of the work of the Army medical officers, released the entire South from the fear of epidemics, the tyranny of the shot-gun quarantine, the periodic suspension of business and the loss of millions of dollars each year? Has not the discovery of the hookworm and the possibility of removing this infection and its results, given new hope to the South of the solution of its labor problem and of its industrial development?

Has Gorgas, in the Canal Zone, trodden on the rights of any one? Yet America is building the canal, where France failed, because applied scientific knowledge is guarding the workman from disease and keeping him alive to do his work. It is about time that the American public understood that the stock objections to advanced sanitary regulations are based on ignorance and misconception of both the law and the facts. A national department of health, like our state boards of health, would be for the study and prevention of disease and the advancement of public health and not for the treatment of individual patients, or for the regulation of the practice of medicine.

IRRATIONAL GOVERNMENTAL DECISIONS ON SODIUM BENZOATE

Last week we referred to the much-discussed question of the use of sodium benzoate as a food preservative. While a great deal has appeared regarding the controverted question of the harmfulness or harmlessness of this chemical, but little attention has been given to the attitude of the United States government on the subject. The fact is, the ruling of the government officials on the question of the use of sodium benzoate in foodstuffs is inconsistent to a degree. They have pronounced the chemical harmless and they permit its use in unlimited quantities in foods, but—and here lies the absurdity—they insist that those manufacturers who use it shall declare on the label both the presence and the proportion of the chemical used. Why should a catsup-maker, for instance, be forced by the government to state the presence and quantity of an ingredient of his product which the same government has officially pronounced harmless and which it permits to be used in any quantity? It is altogether unjust to rule that a manufacturer shall declare the presence and proportion of one ingredient of his product—an ingredient which the government claims to be wholesome—while the presence of any other wholesome ingredients may remain a secret. It is highly probable that if this ruling were brought up to the courts, it would be declared discriminatory and illegal. The only possible explanation for such ridiculous inconsistency is that the government officials who issued this decision knew that they had the wrong side of the controversy and that the American public was not with them. In other words, benzoate of soda is not harmless and the concession to the manufacturers called for a compensating sop to the people. So the officials "hedged" by injecting into their decision a technical restriction in the use of the chemical in foodstuffs.

THE ART OF OMISSION

Robert Louis Stevenson (himself a master of the *ars omissionis*) writes in one of his letters: "There is but one art—to omit! Oh, if I knew how to omit, I would ask no other knowledge. A man who knew how to omit would make an Iliad of a daily newspaper." When all medical writers have learned to omit the useless, the trite, the insignificant and the irrelevant, many manuscript editors will find their occupation gone; but private misfortune will pass unnoticed amid the general rejoicing. *Ars longa, vita brevis;* it takes a long while to learn to be brief; but, on the other hand, nothing will more effectively extend the average span of life than general mastery of the art of omission—in medical literature, at least.

GENEROUS BUT NOT JUST

The story of Dr. Grenfell's heroic and self-sacrificing work among the Labrador fishermen has stirred the entire English-speaking world. American physicians are as proud of him as are his English confrères, since science is international and knows no boundaries. The fact that this noble physician won an American girl as his wife has only increased the sense of pride and proprietorship which all America feels in him. Nor has our enthusiasm limited itself to applause. An American business man, Mr. George B. Cluett of New York, has donated a fine new schooner as an auxiliary to Dr. Grenfell's hospital ship. Two auxiliary yawls have been presented by American college students. Many American dollars have gone to help Dr. Grenfell in his noble work. This is right, and it is to be hoped that means for this purpose may never be lacking. Yet the amazing fact has recently become known that while America has been helping generously to provide hospital ships and surgeons for the fishermen of Newfoundland and Labrador, our own American fishermen, from Cape Ann and Gloucester and Marblehead, have been dependent for aid in time of need on the charity of a French hospital ship. It is not gratifying to our sense of pride and independence to know that at the very time we were giving with a lavish hand to our heroic neighbor on the north, our own sailors were forced to accept from a foreign vessel the aid our own country had withheld. Such neglect of our own can be due only to ignorance and surely, now that the facts are known, there will be no lack of money and men to supply this shameful lack. If Congress does not make provision for a United States hospital ship for our fishermen, private philanthropy should see to it that we no longer suffer under the charge of being unjust and neglectful of our own, at the same time that we are generous with our neighbors.

PROBABLE TAPEWORM INFECTION OF NORTHERN MICHIGAN WATERS

From information received from the State Board of Health of Michigan, which will be embodied in the next publication of that board, we learn that the attention of Dr. Warthin of the Department of Pathology of the University of Michigan has been specially called to the occurrence of the broad tapeworm (*Bothriocephalus latus*) in the mining population of northern Michigan. The large number of Finns and Swedes living in the mining towns might be expected to include cases of this infection, which is said to be very prevalent in Finland and Russia as well as other Baltic states. It also occurs in other European countries and in Japan, but up to recent years has been rarely reported in this country. Prior to 1888 but one case had been reported (by Leidy), though undoubtedly others had occurred; and a large tapeworm was certainly not unknown in Alaska in the sixties among the Russian and creole residents, which by them was attributed to the eating of salmon. Up to 1907 only thirty cases had been reported in the United States, according to Stiles in Osler's "Modern Medicine." Stiles pointed out, however, that it might very likely become more frequent in the fish in some of our lake regions, through infection from the Finnish and Swedish immigrants, and it appears from Dr. Warthin's report that this has already taken place. He finds that children who have been brought to this country as nursing infants have become infected after the age of puberty and it is improbable that they could have brought the disease with them at that tender age to develop at so late a period. One case at least is reported of a child 5 years old who had never been out of the country but who had eaten uncooked fish from Portage Lake. This is itself a sort of arm or inlet of Lake Superior which is probably also contaminated. The *Bothriocephalus* is the most formidable of the tapeworms—one of the largest, if not the largest, and most rapid in its growth—and is capable of causing serious symptoms. The danger, of course, lies in the eating of fish uncooked, but there is a large market for smoked lake whitefish and herring, which are probably often eaten without cooking, or without cooking enough to destroy the parasites. This is especially likely to occur when a new purchaser is informed that cooking is unnecessary. The report to the Michigan Board of Health concludes with a statement of the belief that the infection of the northern waters has already occurred, all the necessary conditions being present, though the larvæ have not yet been actually demonstrated in the fish or its organs. It is recommended that a thorough investigation be made, that measures be taken to prevent the contamination of the waters by the passage of feces of infected persons through sewage, and that warning be given against eating fish — unless thoroughly cooked—which has been caught in localities where the parasite has been found. Only thorough cooking will destroy the larvæ and prevent infection. Smoking, salting and drying are insufficient. The matter is one which has more than a simple local interest, as the Lake Superior fisheries furnish a large proportion of the choicest fresh water fish used in the northern states. A general infection of Lake Superior fish could hardly be kept from spreading to the other lakes and thus greatly increasing the evil.

PATENT-MEDICINE EX-CONGRESSMAN IN THE MESHES OF THE LAW

Our readers were probably not greatly surprised at the announcement in the daily press a few days ago that ex-congressman H. M. Coudrey of Missouri had been arrested on a charge of using the mails to defraud. The alleged misuse of the mails was in connection with the business of the Continental Life Assurance Company and the International Fire Assurance Company. Coudrey's activities in the "patent-medicine" business were discussed in THE JOURNAL, March 30, 1907, p. 1121. At that time, in addition to being an insurance agent and a member of Congress, he was president of the Labordine Pharmacal Company. This company was engaged in the exploitation of about as brazen a fraud as has been perpetrated on the public and the medical profession; it claimed to have a "purely vegetable antipyretic" which was also "a purely vegetable cardiac stimulant." As the analyses made for the Council on Pharmacy and Chemistry showed, this product—Labordine—consisted largely of acetanilid. Coudrey attracted a certain amount of attention in Congress as the author, or introducer, of a number of freak bills including one relating to the Pharmacopeia which was quite generally pronounced "unintelligible," but which probably had a very definite meaning to some people. The point of immediate interest now, however, is whether there are men in the present Congress who have affiliations with such concerns as the Labordine Pharmacal Company; the debates at the coming session of Congress on the proposed, and much-needed, amendment to the Food and Drugs Act and the department of health bills will be followed with much interest from this standpoint.

CHAMLEE GOES TO CALIFORNIA ?

We recently called attention to the fact that S. R. Chamlee, who, until the government interfered, conducted a cancer cure fraud in St. Louis, had opened an office in Chicago. We also noted that Chamlee was advertising for a registered physician so that he might carry on his nefarious work under the protection of the law. We learn from the secretary of the Illinois State Board of Health that as soon as the board's attention was called to the fact that Chamlee was in Chicago, inspectors were sent to investigate the concern. The quack had not yet succeeded in getting his legalized stool-pigeons—in the form of registered physicians—and offered to treat these inspectors, who, he thought, were patients, and accepted a fee therefor. The State Board of Health immediately commenced suit against him and on November 1, Chamlee was fined $100 and costs. He paid the fine and announced his intention of going to California to spend the winter. In the Chicago *Examiner*, November 5, however, we find an advertisement of Chamlee's in which the names of "Drs. Hurford and McKeon" appear. Evidently this faker has been able to find two physicians who are willing to barter their birthright of professional decency for a consideration. It now remains to be seen whether the Illinois law will permit such men to practice. Chamlee's alleged intention of going to California arouses the suspicion that possibly that state is a better haven for quacks than Illinois. It will be remembered that at the time Chamlee was convicted of fraud by the United States Government he had offices both in Los Angeles and St. Louis. We understand he is still running the Los Angeles office. It might be well for the authorities in that state to take a page out of the note-books of Illinois and Missouri. One of the most crying needs of to-day is more aggressive action on the part of state officials. The tendency has been and to a large degree, still is, to allow the federal government to shoulder the responsibility for the prosecution of such vultures as Chamlee.

Medical News

DISTRICT OF COLUMBIA

Building for Physicians.—The Professional Building is the latest innovation in the way of structures in Washington. The four-story house, formerly the home of Justice Peckham of the U. S. Supreme Court, has been remodeled and will be utilized as an office building exclusively for physicians.

ILLINOIS

New Hospital In Cairo.—Dr. Alpheus A. Bondurant has completed arrangements for the erection of a new hospital on Seventh Street, to cost about $50,000. The building will be fire-proof, with the latest ideas as to sanitation, ventilation, etc., and will contain about forty private rooms, besides four wards. It is expected to be ready to receive patients next summer.

County Antituberculosis Society Formed.—At a meeting held in Urbana, October 24, the Champaign County Association for the Prevention of Tuberculosis was organized. Hon. J. O. Cunningham, Urbana, was elected as temporary chairman, and Prof. W. W. Earnest, Champaign, temporary secretary. A committee on organization was appointed, to report in two weeks.

Deaths of the First Half-Year.—According to the reports of the State Board of Health, pneumonia was the chief cause of deaths during the six months ended July 1. The percentages of the chief death causes were as follows: pneumonia, 14.06; tuberculosis, 6.28; influenza, 2.04; typhoid fever, 1.38; measles, 1.17; diphtheria, 1.1; whooping-cough, .9, and scarlet fever, .7.

Personal.—Dr. Faith E. Spangler has been appointed junior physician at the Cook County Hospital for the Insane, Dunning.——Dr. O. W. Michael, Muncie, is reported to be seriously ill.——Dr. Watson W. Gailey, Bloomington, who was operated on for appendicitis at the Brokaw Hospital, October 26, is reported to be doing well.——Dr. Albert E. Campbell, Clinton, has been appointed sanitary inspector of the Illinois Central System. The duties of this position includes the maintenance of healthful surroundings for employees and patrons of the railroad.——Whiteside Medical Society held a special meeting at Fulton, November 9, in honor of Dr. Charles A. Griswold, Fulton, the oldest physician in the county.

Hospital Dedication.—Elaborate exercises marked the dedication of the Granite City Sisters' Hospital, October 12. The institution, which was formerly known as the City Hospital, was dedicated to the Franciscan Sisters and formal possession was taken. Patients applying for treatment in the hospital will be permitted to choose their own attendants and the institution will have no medical staff. Accommodation is provided for forty-eight patients.

State Tuberculosis Association Meeting.—The annual meeting of the Illinois State Association for the Prevention of Tuberculosis was held in Chicago, October 31, and the following officers were elected: president, Dr. William A. Evans, Chicago; vice-presidents, Drs. Tully O. Hardesty, Jacksonville, and George Thomas Palmer, Springfield; secretary, Mr. James Minnick, Chicago, and treasurer, Mr. David R. Forgan, Chicago. The association plans to secure the cooperation of the women's clubs of the state in a survey of the tuberculosis situation, and will be asked to obtain the number of deaths caused by tuberculosis during 1910; the number of cases of living tuberculosis; the number of cases needing material assistance, and the number of patients cared for at poorhouses, asylums, jails, reform schools, hospitals and sanatoriums. Dr. St. Elmo M. Sala, Rock Island, was elected a member of the Central Council.

Chicago

Statue to Dr. Senn.—At a meeting of the Senn Club, October 31, plans were extended for a bronze statue, to the memory of Dr. Senn, to be placed in Lincoln Park. The statue is to cost $25,000, and the funds for this purpose are to be sought by subscriptions from physicians.

Additional Appropriation for Health Department Needed.—Health Commissioner Young has asked an increase in the appropriation of $180,000 for payroll and expansion purposes. The board intends to create a board of control to take charge of the city hospitals and lodging-houses, and the proper licensing and inspection of hospitals.

IOWA

New Medical Association.—A medical association has been organized in Decorah, which includes the physicians of the counties of Allamakee, Winneshiek, Howard, Chickasaw, Fayette and Clayton, and the following officers have been elected: president, Dr. Philo M. Jewell, Decorah; vice-president, Dr. E. W. Johnston, Alta Vista, and secretary-treasurer, Dr. William C. Hess, Cresco.

Personal.—Dr. Harry E. Kirschner, for four years superintendent of the State Sanatorium for the treatment of tuberculosis, Oakdale, has resigned, and will remove to California. ——Dr. Edward Hornibrook, Cherokee, was the guest of honor at a banquet in Cherokee, October 30, on the occasion of the fiftieth anniversary of his entrance into practice. A testimonial, engrossed on parchment, and setting forth that Dr. Hornibrook had well and faithfully performed his duties to the sick and afflicted for fifty years, and signed by all the members of the Cherokee County Medical Society, was presented to Dr. Hornibrook.——Drs. Thomas F. Duhigg, Archelaus G. Field, Lewis Schooler and James W. Osborn, all of Des Moines, have been appointed a committee to write the history of the Polk County Medical Society.——Dr. Wilton W. McCarthy, Des Moines, was obliged to undergo enucleation of an eye, as the result of a burn from a cinder two weeks previously.

KENTUCKY

Out-Door School to be Established.—The Board of Education of Louisville is planning to establish an out-door school for anemic and debilitated children, and Dr. James W. Guest has offered a site on which a building for this purpose may be erected.

State Society Officers.—The list of officers of the Kentucky State Medical Association, which appeared in The Journal of last week, was incomplete as regards the president and president-elect. It should have read: president, Dr. James Givens Carpenter, Stanford; president-elect, Dr. David O. Hancock, Henderson.

Tuberculosis Tax.—A contract has been made between the city of Louisville, by its general council, and the board of trustees of the Tuberculosis Hospital, whereby the board agrees to care for all the tuberculosis patients of the city. The city is to raise money for defraying the necessary expenses by a tax not to exceed 2 cents on each $100. Heretofore the city has made an appropriation each year and has cared for the patients at the City Hospital, but a law was passed by the last legislature authorizing the city to raise money by taxation for this purpose.

Health Exhibit Car.—The free traveling health exhibit car of the Kentucky Association for the Study and Prevention of Tuberculosis left November 4 for a trip through the extreme eastern portion of the state. The trip will occupy twenty-one days and the car will visit twenty cities and fourteen counties. In each city visited lectures on tuberculosis will be given and a Christmas seal committee organized, to take charge of the holiday work of the association.

MARYLAND

Baltimore

Personal.—Drs. William H. Pannebaker and J. George Schmetzer, who have been ill with typhoid fever, have recovered.——Dr. and Mrs. Henry O. Reik and Dr. A. J. Neilson have returned from Europe.

Hospital Association Organized.—A hospital association has been organized by the citizens of Highlandtown and Canton for the purpose of establishing a hospital for these suburbs. The capital stock is $30,000.

Medical Inspection of Public Schools.—The health department announces that the medical inspection of the public schools will commence next week. The inspection of the parochial schools, which commenced October 1, is almost finished.

MASSACHUSETTS

Surgical Instructors Resign.—It is announced in the daily press that Dr. David D. Scannell, chief surgeon at the Boston City Hospital has resigned as professor of surgery in Tufts College of Medicine, Boston, and that every instructor in the surgical department of the school has also resigned, as a protest against what they term a gross slight inflicted on Dr. Scannell.

Septic Sore Throat.—At the meeting of the Suffolk District Medical Society, October 28, Prof. C. E. A. Winslow of New York who has made a most careful study of the epidemic which was so serious in Boston, Brookline and Cambridge last May, asserted that it was a disease new in this part of the world. It is of frequent occurrence in England and is named by him "septic sore throat." This epidemic apparently started in Hudson, Marlboro and Southboro and was almost certainly conveyed to Boston by the milk-supply. The experts who spoke at the meeting were agreed that the only safeguard against other outbreaks is in the pasteurization of the milk. The mortality of the epidemic studied reached more than fifty, largely among old people.

MICHIGAN

Medallion Presented.—At the meeting of the Wayne County Medical Society, October 21, Frank Buttrick presented to the society a medallion of the late Dr. David Osborne Farrand, a member of the society, who died in 1883.

Physicians Adopt Auto-Shield.—A shield with a background of bright red and the cross of St. George deeply outlined in black in the center, was the device adopted by the Wayne County Medical Society, October 30, as a distinguishing mark for physicians' automobiles. In the center of the cross appears the registered number of the physician.

Personal.—D. E. McClure, Muskegon, has been appointed deputy superintendent of the State Board of Health, vice Dr. E. L. Ward, resigned.——Physicians of Grand Rapids gave a banquet, October 26, in honor of Dr. Joseph Bascom Griswold, who has been a practitioner of Grand Rapids for forty years. Dr. Eugene Boise presided as toastmaster.——Drs. Frank W. Garber and George L. Le Fevre, Muskegon, have returned from Europe.——Dr. Victor C. Vaughan, Ann Arbor, has returned after a summer spent in Germany.——Drs. William A. Lemire, Michael P. Fenelon and Arthur S. Kitchen, all of Escanaba, have been elected official physicians of the Delta County Hospital and county physicians.——Dr. Abraham Goodfellow, Clio, suffered a cerebral hemorrhage, October 8.

MINNESOTA

Personal.—Dr. Robert Retzer has been appointed assistant professor of anatomy in the University of Chicago.——Dr. William Frisbie Lewis, Mankato, celebrated his eighty-second birthday anniversary at his home in Palo Alto, Cal.

Appropriations for Sanatorium.—The commissioners of Otter Tail County have appointed a committee to ascertain the cost, prepare plans and select a site for a county tuberculosis sanatorium, for which from $6,000 to $10,000 is to be appropriated.

Physicians' Building.—The Lowry Building, Minneapolis, a thirteen-story structure, providing for twenty-four office sections on each floor, is practically completed and tenants are already beginning to move in. The building is designed entirely for the use of physicians and dentists.

Society Meeting.—At the annual meeting of the Mower County Medical Association held in Austin, October 11, Dr. Ernest V. Smith, Adams, was elected president; Dr. G. M. Frank Rogers, Austin, vice-president; Dr. Peter T. Torkelson, Lyle, secretary; Dr. George J. Schottler, Dexter, treasurer, and Dr. Ralph S. Mitchell, Grand Meadow, delegate to the state association.

NEBRASKA

Typhoid Epidemic in Lincoln.—On account of the prevalence of typhoid fever in Lincoln, the local health authorities have requested aid from Washington and Passed Assistant Surgeon Leslie L. Lumsden, U. S. P. H. and M.-H. Service, who was detailed to go to Lincoln and make investigation into the epidemic and its causation, is now there conducting the investigation.

Personal.—Dr. Abraham T. Hubbell, Wood River, who has been seriously ill with erysipelas, is convalescent.——Dr. John B. Lichtenwallner, Dunbar, was given a farewell banquet, October 27, on the occasion of his leaving to settle in Omaha.

Republican Valley Physicians Meet.—The annual meeting of the Republican Valley Medical Association was held at Alma, October 26. The society decided to hold its next meeting in Holdrege in May, 1912, elected Dr. Robert S. Mitchell, Red Cloud, president, and Dr. Henry Farrell, Axtell, vice-president, and reelected Dr. Joseph N. Campbell, Stamford, secretary, and Dr. William D. Shields, Holdrege, treasurer.

NEW YORK

Hospital to be Sold.—Hempstead Hospital, Mineola, L. I., is to be sold at auction in order to satisfy claims against the institution.

Approves Tuberculosis Hospital.—The state authorities have approved the application of the Civic League of Ossining to establish a tuberculosis hospital.

Personal.—Dr. James J. Grady, Elmhurst, has resigned to take charge of a hospital for a copper mining company in Peru, South America.——Dr. Thomas Ordway, Albany, was given an impromptu dinner by the faculty of the Albany Medical college and other friends, October 17. Dr. Ordway has been connected with the Bender Laboratory for about twenty years, but is soon to become director of the cancer research laboratory of Harvard University.——Dr. Edward F. Hurd has been elected president of the Freeport Board of Health.

New York City

Lowest City Death-Rate.—The lowest death-rate since the formation of the Greater New York in 1898 was reported for the week ended October 28, the rate for this week being 12.12 per 1,000 population, while the rate for the corresponding week of 1910 was 13.53.

New Laboratory Building.—Roosevelt Hospital has had a laboratory under an endowment given by Mrs. E. H. Harriman for the past two years. Recently Dr. Lewis R. Morris offered to erect a suitable building for laboratory work and such a building will be erected in the center of the Roosevelt Hospital premises. Dr. William Gordon Lyle is to have charge of the new institution.

New York Academy of Medicine Committee on Hospital and Municipal Budget.—This committee was formed by the two committees created by act of council and appointment by the president. The work of this reorganized committee has been the investigation in this city of hospital conditions. It is to keep the profession informed in regard to hospital needs, organization and progress, and cooperate with the library in securing hospital literature; it is also to investigate the conditions and needs of those departments of the city which control the public hospitals, viz., the health department, the charities department and the Bellevue and Allied Hospitals, so that the committee can, with proper data, appear before the city authorities and aid in securing needed or opposing unwise appropriations, increasing the efficiency of the city's hospitals. All this is to be done on condition that such investigation and help were desired. The committee reported that if its paid executive committee were continued, it could and ought to assume the work of a council on hygiene, or a committee on public health, and asked for an enlargement of its activities. The council voted to grant the committee the enlarged powers which it asked. Dr. Charles L. Dana is chairman of the committee and Dr. James Alexander Miller, secretary.

OHIO

Loving Library Given to Academy.—By the will of the late Dr. Starling Loving, Columbus, his medical library is bequeathed to the Columbus Academy of Medicine.

Physicians' Buildings.—Plans have been drawn for two buildings in Columbus, to be used entirely for physicians' offices. The one will contain accommodation for twenty-four and the other for twelve physicians.

Conference of Health Officers.—At the thirty-first conference of the State Board of Health with representatives of the local boards of health, in the southern district of Ohio, held in Cincinnati, October 19 and 20, questions of quarantine, disinfection, prevention of tuberculosis, sexual hygiene, and other subjects of vital interest to sanitarians were discussed.

The Fight Against Tuberculosis.—The Cleveland School Board, the Antituberculosis League, the Federation of Women's Clubs, Fresh Air Camp Association, and the Board of Health, held a conference, October 26, and agreed to combine in the movement to stamp out tuberculosis from the schools and to conduct and extend the work now being done in open-air schools.

Physicians Ill or Injured.—Dr. Rufus D. Jacobs, Vinton, fell from a Hocking Valley train near that place, October 28, and had both legs cut off.——Dr. Thomas A. Weaver, Orrville, is reported to be ill with typhoid fever.——Dr. Robert D. Gibson, Youngstown, who was injured in an automobile accident near Canton, in September, was brought to Youngstown, October 25. He is reported to be improving.——Dr. Charles A. Dunn, Stovertown, suffered a cerebral hemorrhage, October 7.——Dr. Henry H. Havens, Tippecanoe City, was seriously injured in an automobile accident, October 8.——Dr. Edward H. Porter, Tiffin, was operated on for appendicitis, October 11.

Personal.—Dr. Allen A. Taylor, Toledo, has gone to Florida, where he expects to make his home.——Dr. John D. O'Brien, Massillon, has resigned as head of the Strongsville Sanatorium, and will practice in Canton.——Dr. Corydon O. Beardsley, Ottawa, has been appointed surgeon to the local pension examining board, vice Dr. Alva L. Paul, deceased.——Dr. George H. Wilson, Painesville, has been appointed chief surgeon in the Consolidated Coal Company, Cumberland, Md.——Dr. Edson C. Brown has resigned as chief of the medical staff of the Massillon State Hospital and will practice in Mansfield.——Dr. Herbert M. Platter and family, Columbus, have returned from Europe.

Cincinnati

Academy of Medicine Entertains Druggists.—The Cincinnati Academy of Medicine at its meeting, October 30, entertained the Ohio Valley Druggists' Association and the Hamilton County Medical Society. The questions discussed at the joint meeting were such as would advance the cause of legitimate pharmacy.

Open-Air Schools Ready.—The two open-air schools—one for anemic and the other for tuberculous children—were opened October 30. The school for anemics is located at the First Intermediate school and has an initial attendance of about sixty; the school for tuberculous children is located at the Branch Hospital and commenced with twenty children in attendance.

Personal.—Dr. and Mrs. Christian R. Holmes have returned from Europe.——Drs. William Gillespie and Otto V. Huffman have been appointed members of the junior staff of the Cincinnati City Hospital on the gynecological and obstetrical service, vice Dr. Robert Thomas, resigned.——Dr. Charles A. Stammel has been appointed resident physician at the Industrial School for Boys, Lancaster, vice Dr. Julius G. Stammel, resigned.——Dr. Samuel S. Tomlinson, on his own request, is said to have been committed to the Longview State Hospital, October 19.

PENNSYLVANIA

Progress on State Sanatorium.—The dining hall of the largest of the buildings of the sanatorium at the Summit, Cresson, will be ready for occupancy, November 15. The east ward will be finished a few days later and the remainder of the buildings will, it is said, be completed by January 1.

Personal.—Dr. and Mrs. Carlisle E. McKee, Braddock, sailed for Europe, October 23.——Dr. John C. Hoye, Newcastle, was attacked by robbers in New York City, November 2, and sustained a severe fracture of the skull.——Dr. Samuel H. Gilliland, Harrisburg, has been appointed director of the state department of health laboratories.——Dr. Maurice E. Heck has resigned as intern in the Harrisburg Hospital and will locate in Florida.——Dr. William C. Le Compte has succeeded Dr. William Martin as local surgeon of the Pennsylvania System at Bristol.

Tuberculosis Exhibit at Pittsburgh.—The Tuberculosis League of Pittsburgh had an exhibit at the recent Industrial Exposition in that city illustrating preventive measures in human and bovine tuberculosis and infant mortality. During the seven weeks that the exposition was open, the booth was visited by 70,000 people.

Censorial District Meeting.—The eighth annual meeting of the Seventeenth Censorial District of the Medical Society of the State of Pennsylvania, including Montour, Snyder, Northumberland and Columbia counties, was held at Selins Grove, September 8. Danville was chosen as the next place of meeting and Dr. John B. Cressinger, of Sunbury, was elected president, and Dr. Luther B. Kline, of Catawissa, secretary. Resolutions were adopted heartily endorsing and supporting Dr. Harvey W. Wiley in his honest and heroic efforts impartially to enforce the Pure Food and Drugs Act.

Philadelphia

Weir Mitchell Lectures.—The fourth of the Weir Mitchell Lectures of the College of Physicians was delivered November 3, by Dr. William T. Porter of the Harvard Medical School on "Shock."

Alumni Dinner.—The Philadelphia Alumni of the medical department of the University of Pennsylvania will hold their annual banquet, November 18. Among the guests will be the new members of the medical staff of the university.

Solarium for Hospital.—Through the executors of the estate of Mrs. Catharine C. Middleton, $10,000 has been given to the Jefferson Medical College Hospital for the erection of a solarium for children in memory of Samuel W. Middleton.

Gift of Hospital.—At the golden jubilee celebration of the John Wanamaker Store, held in the store, October 28, the site of John Wanamaker's birthplace in the southern part of the city, which the 6,050 employees had purchased, was presented to him. Mr. Wanamaker announced that he would place this property, together with ground in the neighborhood which he would purchase, in trust with three trustees from different departments of the store, and would thereon erect a great hospital for suffering children, to be called the Robert C. Ogden Hospital, after a former partner.

Personal.—Dr. Herman A. Brav announces that he has given up the practice of general medicine and will henceforth confine his work to the treatment of diseases of the rectum.——Dr. W. W. Cadbury, dean and professor of medicine and pathology in the University Medical School, Canton, China, was the guest of honor at a banquet, held in Houston Hall, October 30.——Dr. Joseph S. Neff has resigned as president of the Philadelphia Housing Commission and has been succeeded by Mr. George W. Norris.——Dr. Charles E. Treibley has been appointed physician at the Carlisle Indian School.——Dr. Elliston J. Morris fractured his left arm in an automobile accident, near Egg Harbor, October 8.——Dr. Richard H. Harte has returned from Europe.

Larger Force Needed for Health Department.—The department of Public Health and Charities has been greatly handicapped by inadequate staffs and Dr. Joseph S. Neff, the director of the department, has asked city councils for additional assistance. Dr. Neff plans the reorganization of the nuisance inspection division, divorcing it entirely from the tenement house division. B. J. Newman, secretary of the Philadelphia Housing Commission, in endorsing Dr. Neff's request for additional sanitary and nuisance inspection, said that not a single actual inspection of conditions in houses already built and occupied has been made this year, owing to the necessity of putting inspectors and fumigators at clerical work in the offices of the department. Dr. Neff hopes that the staff of visiting nurses will be increased to forty. Eight are on the staff now, but their work is confined to a restricted territory.

VIRGINIA

Meeting of State Society.—The forty-second annual meeting of the Medical Society of Virginia was held in Richmond, October 24-27, under the presidency of Dr. Otho C. Wright, Jarratt. The society took official cognizance of the Carrington-Mann question by adopting a resolution "That it is the sense of the Medical Society of Virginia that the state lost a most valuable and capable officer when Dr. Charles V. Carrington, Richmond, was not reelected surgeon of the state penitentiary." The following officers were elected: president, Dr. Hugh M. Taylor, Richmond; vice-presidents, Drs. Samuel Lile, Lynchburg; Joseph Grice, Portsmouth, and Samuel B. Moore, Alexandria; secretary; Dr. Paulus A. Irving, Richmond (reelected); treasurer, Dr. Greer Baughman, Richmond (reelected); councilors, Drs. Alfred L. Gray and Charles V. Carrington, both of Richmond; and delegates to the American Medical Association, Drs. William E. Anderson, Farmville, and John Staige Davis, Charlottesville. Norfolk was selected as the next place of meeting.

Control of Communicable Diseases.—A committee from the Norfolk Medical Society, composed of Drs. Lomax Gwathmey, Lawrence T. Royster, Herbert Old, William L. Harris, Charles R. Grandy and Beverly R. Kennon, have recommended concerning the extension and enforcement of health ordinances: that a medical inspector be employed by the health department, and that a hospital for contagious diseases, aside from smallpox, be at once provided.

Public Health Officers Meet.—The Virginia Public Health Association, at its meeting in Richmond, October 26, elected the following officers: president, Dr. Ernest C. Levy, Richmond; vice-presidents, Drs. Powhatan S. Schenck, Norfolk, and Jesse M. Shackelford, Martinsville; secretary-treasurer, Dr. Lucien Lofton, Emporia; and delegates to the Public Health Association, Drs. Ernest C. Levy, Richmond, Powhatan S. Schenck, Norfolk, and Allen W. Freeman, Richmond.

WASHINGTON

Personal.—The Spokane Medical Association has appointed the following staff for the new tuberculosis sanatorium: Drs. Frank Hinman, Henry Power, Arthur E. Johnson, Alexander R. Lundgren, Herman P. Marshall and A. P. Tilmont. Drs. Ronald A. Greene and William S. Frost were also appointed consultants in complications of the eye, ear and throat.——Dr. James E. Crichton has been appointed a member of the commission to investigate and report on tuberculosis in Seattle.——Dr. Xenophon L. Anthony, Spokane, who was operated on in the Sacred Heart Hospital, October 21, for appendicitis, is reported convalescent.——Dr. A. E. Stuht, Colfax, has resigned as city health officer.——Dr. Fred R. Hedges, Everett, who was operated on for appendicitis at the New Providence Hospital, Seattle, is reported convalescent.——Dr. Elmer E. Heg, Seattle, state health commissioner and secretary of the State Board of Health, has resigned on account of the ill health of his wife.

WEST VIRGINIA

State Association Meeting.—At the annual meeting of the West Virginia State Medical Association held in White Sulphur Springs, the following officers were elected: president, Dr. Charles O. Henry, Fairmont; vice-presidents, Drs. Richard E. Venning, Charlestown; Charles O'Grady, Charleston, and W. Hoddis Daniels, Elkins; secretary, Dr. Arthur P. Butt, Davis (reelected); treasurer, Dr. Hugh G. Nicholson, Charleston; councilors, first district, Dr. Henry R. Johnson, Fairmont; second district, Dr. Richard H. Edmundson, Morgantown; third district, Dr. Benjamin B. Wheeler, McKendrie; fourth district, Dr. George D. Jeffers, Parkersburg; fifth district, Dr. Joseph E. Rader, Huntington; delegates to the American Medical Association, Drs. Peter A. Haley, Charleston, and Frank L. Hupp, Wheeling; and alternates, Drs. Vincent T. Churchman, Charleston, and Charles A. Wingerter, Wheeling. Webster Springs was selected as the next place of meeting.

WISCONSIN

Antitoxin Distributed.—During the two years since free distribution of diphtheria antitoxin to the poor of the state has been made, 4,297 packages of antitoxin have been distributed.

Ill and Injured.—Dr. Charles E. Hildreth, Lena, Ill., who has been ill in Milwaukee for several weeks, has recovered and resumed practice.——Dr. William T. Rinehart, Ashland, is reported to be in critical condition following an abdominal section.

Waukesha Wants Hospital.—A formal appeal has been made to the city council by the physicians of Waukesha to take up and aid the project for a city hospital, for which a fund of $5,000 was subscribed several months ago through the efforts of the local medical society.

Personal.—Dr. E. Baumgartner has been appointed instructor in anatomy in the University of Wisconsin.——The board of trustees of the Milwaukee County poor have reelected the following officers: Dr. Albert F. Young, county physician, and Dr. Louis F. Klemm in charge of the west side; Dr. William F. Lochemes, south side; Dr. Charles A. Fidler, Cudahy; Dr. John H. Rohr, North Milwaukee, and Dr. T. P.

Physicians' Building.—The Lowry Building, Minneapolis, a thirteen-story structure, providing for twenty-four office sections on each floor, is practically completed and tenants are already beginning to move in. The building is designed entirely for the use of physicians and dentists.

Society Meeting.—At the annual meeting of the Mower County Medical Association held in Austin, October 11, Dr. Ernest V. Smith, Adams, was elected president; Dr. G. M. Frank Rogers, Austin, vice-president; Dr. Peter T. Torkelson, Lyle, secretary; Dr. George J. Schottler, Dexter, treasurer, and Dr. Ralph S. Mitchell, Grand Meadow, delegate to the state association.

NEBRASKA

Typhoid Epidemic in Lincoln.—On account of the prevalence of typhoid fever in Lincoln, the local health authorities have requested aid from Washington and Passed Assistant Surgeon Leslie L. Lumsden, U. S. P. H. and M.-H. Service, who was detailed to go to Lincoln and make investigation into the epidemic and its causation, is now there conducting the investigation.

Personal.—Dr. Abraham T. Hubbell, Wood River, who has been seriously ill with erysipelas, is convalescent.——Dr. John B. Lichtenwallner, Dunbar, was given a farewell banquet, October 27, on the occasion of his leaving to settle in Omaha.

Republican Valley Physicians Meet.—The annual meeting of the Republican Valley Medical Association was held at Alma, October 26. The society decided to hold its next meeting in Holdrege in May, 1912, elected Dr. Robert S. Mitchell, Red Cloud, president, and Dr. Henry Farrell, Axtell, vice-president, and reelected Dr. Joseph N. Campbell, Stamford, secretary, and Dr. William D. Shields, Holdrege, treasurer.

NEW YORK

Hospital to be Sold.—Hempstead Hospital, Mineola, L. I., is to be sold at auction in order to satisfy claims against the institution.

Approves Tuberculosis Hospital.—The state authorities have approved the application of the Civic League of Ossining to establish a tuberculosis hospital.

Personal.—Dr. James J. Grady, Elmhurst, has resigned to take charge of a hospital for a copper mining company in Peru, South America.——Dr. Thomas Ordway, Albany, was given an impromptu dinner by the faculty of the Albany Medical college and other friends, October 17. Dr. Ordway has been connected with the Bender Laboratory for about twenty years, but is soon to become director of the cancer research laboratory of Harvard University.——Dr. Edward F. Hurd has been elected president of the Freeport Board of Health.

New York City

Lowest City Death-Rate.—The lowest death-rate since the formation of the Greater New York in 1898 was reported for the week ended October 28, the rate for this week being 12.12 per 1,000 population, while the rate for the corresponding week of 1910 was 13.53.

New Laboratory Building.—Roosevelt Hospital has had a laboratory under an endowment given by Mrs. E. H. Harriman for the past two years. Recently Dr. Lewis R. Morris offered to erect a suitable building for laboratory work and such a building will be erected in the center of the Roosevelt Hospital premises. Dr. William Gordon Lyle is to have charge of the new institution.

New York Academy of Medicine Committee on Hospital and Municipal Budget.—This committee was formed by the two committees created by act of council and appointment by the president. The work of this reorganized committee has been the investigation in this city of hospital conditions. It is to keep the profession informed in regard to hospital needs, organization and progress, and cooperate with the library in securing hospital literature; it is also to investigate the conditions and needs of those departments of the city which control the public hospitals, viz., the health department, the charities department and the Bellevue and Allied Hospitals, so that the committee can, with proper data, appear before the city authorities and aid in securing needed or opposing unwise appropriations, increasing the efficiency of the city's hospitals. All this is to be done on condition that such investigation and help were desired. The committee reported that if its paid executive committee were continued, it could and ought to assume the work of a council on hygiene, or a committee on public health, and asked for an enlargement of its activities. The council voted to grant the committee the enlarged powers which it asked. Dr. Charles L. Dana is chairman of the committee and Dr. James Alexander Miller, secretary.

OHIO

Loving Library Given to Academy.—By the will of the late Dr. Starling Loving, Columbus, his medical library is bequeathed to the Columbus Academy of Medicine.

Physicians' Buildings.—Plans have been drawn for two buildings in Columbus, to be used entirely for physicians' offices. The one will contain accommodation for twenty-four and the other for twelve physicians.

Conference of Health Officers.—At the thirty-first conference of the State Board of Health with representatives of the local boards of health, in the southern district of Ohio, held in Cincinnati, October 19 and 20, questions of quarantine, disinfection, prevention of tuberculosis, sexual hygiene, and other subjects of vital interest to sanitarians were discussed.

The Fight Against Tuberculosis.—The Cleveland School Board, the Antituberculosis League, the Federation of Women's Clubs, Fresh Air Camp Association, and the Board of Health, held a conference, October 26, and agreed to combine in the movement to stamp out tuberculosis from the schools and to conduct and extend the work now being done in open-air schools.

Physicians Ill or Injured.—Dr. Rufus D. Jacobs, Vinton, fell from a Hocking Valley train near that place, October 28, and had both legs cut off.——Dr. Thomas A. Weaver, Orrville, is reported to be ill with typhoid fever.——Dr. Robert D. Gibson, Youngstown, who was injured in an automobile accident near Canton, in September, was brought to Youngstown, October 25. He is reported to be improving.——Dr. Charles A. Dunn, Stovertown, suffered a cerebral hemorrhage, October 7.——Dr. Henry H. Havens, Tippecanoe City, was seriously injured in an automobile accident, October 8.——Dr. Edward H. Porter, Tiffin, was operated on for appendicitis, October 11.

Personal.—Dr. Allen A. Taylor, Toledo, has gone to Florida, where he expects to make his home.——Dr. John D. O'Brien, Massillon, has resigned as head of the Strongsville Sanatorium, and will practice in Canton.——Dr. Corydon O. Beardsley, Ottawa, has been appointed surgeon to the local pension examining board, vice Dr. Alva L. Paul, deceased.——Dr. George H. Wilson, Painesville, has been appointed chief surgeon in the Consolidated Coal Company, Cumberland, Md.——Dr. Edson C. Brown has resigned as chief of the medical staff of the Massillon State Hospital and will practice in Mansfield.——Dr. Herbert M. Platter and family, Columbus, have returned from Europe.

Cincinnati

Academy of Medicine Entertains Druggists.—The Cincinnati Academy of Medicine at its meeting, October 30, entertained the Ohio Valley Druggists' Association and the Hamilton County Medical Society. The questions discussed at the joint meeting were such as would advance the cause of legitimate pharmacy.

Open-Air Schools Ready.—The two open-air schools—one for anemic and the other for tuberculous children—were opened October 30. The school for anemics is located at the First Intermediate school and has an initial attendance of about sixty; the school for tuberculous children is located at the Branch Hospital and commenced with twenty children in attendance.

Personal.—Dr. and Mrs. Christian R. Holmes have returned from Europe.——Drs. William Gillespie and Otto V. Huffman have been appointed members of the junior staff of the Cincinnati City Hospital on the gynecological and obstetrical service, vice Dr. Robert Thomas, resigned.——Dr. Charles A. Stammel has been appointed resident physician at the Industrial School for Boys, Lancaster, vice Dr. Julius G. Stammel, resigned.——Dr. Samuel S. Tomlinson, on his own request, is said to have been committed to the Longview State Hospital, October 19.

PENNSYLVANIA

Progress on State Sanatorium.—The dining hall of the largest of the buildings of the sanatorium at the Summit, Cresson, will be ready for occupancy, November 15. The east ward will be finished a few days later and the remainder of the buildings will, it is said, be completed by January 1.

Personal.—Dr. and Mrs. Carlisle E. McKee, Braddock, sailed for Europe, October 23.——Dr. John C. Hoye, Newcastle, was attacked by robbers in New York City, November 2, and sustained a severe fracture of the skull.——Dr. Samuel H. Gilliland, Harrisburg, has been appointed director of the state department of health laboratories.——Dr. Maurice E. Heck has resigned as intern in the Harrisburg Hospital and will locate in Florida.——Dr. William C. Le Compte has succeeded Dr. William Martin as local surgeon of the Pennsylvania System at Bristol.

Tuberculosis Exhibit at Pittsburgh.—The Tuberculosis League of Pittsburgh had an exhibit at the recent Industrial Exposition in that city illustrating preventive measures in human and bovine tuberculosis and infant mortality. During the seven weeks that the exposition was open, the booth was visited by 70,000 people.

Censorial District Meeting.—The eighth annual meeting of the Seventeenth Censorial District of the Medical Society of the State of Pennsylvania, including Montour, Snyder, Northumberland and Columbia counties, was held at Selins Grove, September 8. Danville was chosen as the next place of meeting and Dr. John B. Cressinger, of Sunbury, was elected president, and Dr. Luther B. Kline, of Catawissa, secretary. Resolutions were adopted heartily endorsing and supporting Dr. Harvey W. Wiley in his honest and heroic efforts impartially to enforce the Pure Food and Drugs Act.

Philadelphia

Weir Mitchell Lectures.—The fourth of the Weir Mitchell Lectures of the College of Physicians was delivered November 3, by Dr. William T. Porter of the Harvard Medical School on "Shock."

Alumni Dinner.—The Philadelphia Alumni of the medical department of the University of Pennsylvania will hold their annual banquet, November 18. Among the guests will be the new members of the medical staff of the university.

Solarium for Hospital.—Through the executors of the estate of Mrs. Catharine C. Middleton, $10,000 has been given to the Jefferson Medical College Hospital for the erection of a solarium for children in memory of Samuel W. Middleton.

Gift of Hospital.—At the golden jubilee celebration of the John Wanamaker Store, held in the store, October 28, the site of John Wanamaker's birthplace in the southern part of the city, which the 6,050 employees had purchased, was presented to him. Mr. Wanamaker announced that he would place this property, together with ground in the neighborhood which he would purchase, in trust with three trustees from different departments of the store, and would thereon erect a great hospital for suffering children, to be called the Robert C. Ogden Hospital, after a former partner.

Personal.—Dr. Herman A. Brav announces that he has given up the practice of general medicine and will henceforth confine his work to the treatment of diseases of the rectum.——Dr. W. W. Cadbury, dean and professor of medicine and pathology in the University Medical School, Canton, China, was the guest of honor at a banquet, held in Houston Hall, October 30.——Dr. Joseph S. Neff has resigned as president of the Philadelphia Housing Commission and has been succeeded by Mr. George W. Norris.——Dr. Charles E. Treibley has been appointed physician at the Carlisle Indian School.——Dr. Elliston J. Morris fractured his left arm in an automobile accident, near Egg Harbor, October 8.——Dr. Richard H. Harte has returned from Europe.

Larger Force Needed for Health Department.—The department of Public Health and Charities has been greatly handicapped by inadequate staffs and Dr. Joseph S. Neff, the director of the department, has asked city councils for additional assistance. Dr. Neff plans the reorganization of the nuisance inspection division, divorcing it entirely from the tenement house division. B. J. Newman, secretary of the Philadelphia Housing Commission, in endorsing Dr. Neff's request for additional sanitary and nuisance inspection, said that not a single actual inspection of conditions in houses already built and occupied has been made this year, owing to the necessity of putting inspectors and fumigators at clerical work in the offices of the department. Dr. Neff hopes that the staff of visiting nurses will be increased to forty. Eight are on the staff now, but their work is confined to a restricted territory.

VIRGINIA

Meeting of State Society.—The forty-second annual meeting of the Medical Society of Virginia was held in Richmond, October 24-27, under the presidency of Dr. Otho C. Wright, Jarratt. The society took official cognizance of the Carrington-Mann question by adopting a resolution "That it is the sense of the Medical Society of Virginia that the state lost a most valuable and capable officer when Dr. Charles V. Carrington, Richmond, was not reelected surgeon of the state penitentiary." The following officers were elected: president, Dr. Hugh M. Taylor, Richmond; vice-presidents, Drs. Samuel Lile, Lynchburg; Joseph Grice, Portsmouth, and Samuel B. Moore, Alexandria; secretary; Dr. Paulus A. Irving, Richmond (reelected); treasurer, Dr. Greer Baughman, Richmond (reelected); councilors, Drs. Alfred L. Gray and Charles V. Carrington, both of Richmond; and delegates to the American Medical Association, Drs. William E. Anderson, Farmville, and John Staige Davis, Charlottesville. Norfolk was selected as the next place of meeting.

Control of Communicable Diseases.—A committee from the Norfolk Medical Society, composed of Drs. Lomax Gwathmey, Lawrence T. Royster, Herbert Old, William L. Harris, Charles R. Grandy and Beverly R. Kennon, have recommended concerning the extension and enforcement of health ordinances: that a medical inspector be employed by the health department, and that a hospital for contagious diseases, aside from smallpox, be at once provided.

Public Health Officers Meet.—The Virginia Public Health Association, at its meeting in Richmond, October 26, elected the following officers: president, Dr. Ernest C. Levy, Richmond; vice-presidents, Drs. Powhatan S. Schenck, Norfolk, and Jesse M. Shackelford, Martinsville; secretary-treasurer, Dr. Lucien Lofton, Emporia; and delegates to the Public Health Association, Drs. Ernest C. Levy, Richmond, Powhatan S. Schenck, Norfolk, and Allen W. Freeman, Richmond.

WASHINGTON

Personal.—The Spokane Medical Association has appointed the following staff for the new tuberculosis sanatorium: Drs. Frank Hinman, Henry Power, Arthur E. Johnson, Alexander R. Lundgren, Herman P. Marshall and A. P. Tilmont. Drs. Ronald A. Greene and William S. Frost were also appointed consultants in complications of the eye, ear and throat.——Dr. James E. Crichton has been appointed a member of the commission to investigate and report on tuberculosis in Seattle.——Dr. Xenophon L. Anthony, Spokane, who was operated on in the Sacred Heart Hospital, October 21, for appendicitis, is reported convalescent.——Dr. A. E. Stuht, Colfax, has resigned as city health officer.——Dr. Fred R. Hedges, Everett, who was operated on for appendicitis at the New Providence Hospital, Seattle, is reported convalescent.——Dr. Elmer E. Heg, Seattle, state health commissioner and secretary of the State Board of Health, has resigned on account of the ill health of his wife.

WEST VIRGINIA

State Association Meeting.—At the annual meeting of the West Virginia State Medical Association held in White Sulphur Springs, the following officers were elected: president, Dr. Charles O. Henry, Fairmont; vice-presidents, Drs. Richard E. Venning, Charlestown; Charles O'Grady, Charleston, and W. Hoddis Daniels, Elkins; secretary, Dr. Arthur P. Butt, Davis (reelected); treasurer, Dr. Hugh G. Nicholson, Charleston; councilors, first district, Dr. Henry R. Johnson, Fairmont; second district, Dr. Richard H. Edmundson, Morgantown; third district, Dr. Benjamin B. Wheeler, McKendrie; fourth district, Dr. George D. Jeffers, Parkersburg; fifth district, Dr. Joseph E. Rader, Huntington; delegates to the American Medical Association, Drs. Peter A. Haley, Charleston, and Frank L. Hupp, Wheeling; and alternates, Drs. Vincent T. Churchman, Charleston, and Charles A. Wingerter, Wheeling. Webster Springs was selected as the next place of meeting.

WISCONSIN

Antitoxin Distributed.—During the two years since free distribution of diphtheria antitoxin to the poor of the state has been made, 4,297 packages of antitoxin have been distributed.

Ill and Injured.—Dr. Charles E. Hildreth, Lena, Ill., who has been ill in Milwaukee for several weeks, has recovered and resumed practice.——Dr. William T. Rinehart, Ashland, is reported to be in critical condition following an abdominal section.

Waukesha Wants Hospital.—A formal appeal has been made to the city council by the physicians of Waukesha to take up and aid the project for a city hospital, for which a fund of $5,000 was subscribed several months ago through the efforts of the local medical society.

Personal.—Dr. E. Baumgartner has been appointed instructor in anatomy in the University of Wisconsin.——The board of trustees of the Milwaukee County poor have reelected the following officers: Dr. Albert F. Young, county physician, and Dr. Louis F. Klemm in charge of the west side; Dr. William F. Lochemes, south side; Dr. Charles A. Fidler, Cudahy; Dr. John H. Rohr, North Milwaukee, and Dr. T. P.

Grogan, West Allis.——Dr. and Mrs. Andres G. Hovde, Superior, sailed for Europe, October 28.——Dr. Richard E. Davies has succeeded Dr. W. B. Strong as health commissioner of Waukesha.——Dr. David Lloyd Williams, Milwaukee, has been appointed assistant surgeon at the National Volunteer Soldiers' Home, Danville, Ill.——Dr. Max Staehle has been elected president of the State Agricultural Society.——Dr. Sara I. Morris has been appointed medical adviser of women at the University of Wisconsin, vice Dr. J. Helen Dobson, resigned.——Dr. Thomas Fitzgibbons, Milwaukee, has returned from abroad.——Dr. Maurice D. Bird, Marinette, has succeeded Dr. William R. Bell as physician of Marinette County.

GENERAL

Railway Surgeons to Meet.—The twenty-first annual meeting of the New York and New England Association of Railway Surgeons will be held at Hotel Astor, New York City, November 16 and 17, under the presidency of Dr. Frederick A. Goodwin, Binghamton, N. Y.

Militia Men Must Pay for Typhoid Vaccination.—So many applications have been received by the War Department from national guard organizations for the supply of antityphoid serum, that it has been found necessary to abandon its free issue. A circular has been issued informing the guardsmen that hereafter they can obtain the serum at its cash value, approximately 12½ cents for each inoculation, the amount to be charged against the federal allotment of the state for the support of the militia.

Ultraviolet Rays to Purify Water.—Army surgeons in the Philippine Islands report that they have been making successful experiments with a plant consisting of a small dynamo and gasoline engine, carried in the ordinary escort wagon with troops, which has shown itself capable, by the generation of ultraviolet rays, of completely purifying foul water so as to serve daily a quart of sweet drinking water to every man in the regiment. The ultraviolet rays are said to destroy, not only the animal parasites in the water, but also bacteria.

Personal.—Lieutenant-Colonel Jefferson R. Kean, M.C., U. S. Army, has been detailed as a delegate to the International conference to be opened in Paris, November 7, and also to the meeting of the American Public Health Association in Havana, December 4-9.——Surgeon Rupert Blue and Assistant Surgeon George W. McCoy, U. S. P. H. and M.-H. Service, sailed from San Francisco, November 4, for Honolulu, Hawaii, Dr. Blue to preside over the quarantine station, and Dr. McCoy to assume command of the leprosy investigation station on the Island of Molokai.——Dr. Aristides Agramonte, Havana, sailed from New York for Holland, October 31.

Plague and Yellow Fever.—The *Canal Record*, October 25, reports a death at Ancon Hospital, October 17, from bubonic plague. The victim was a mechanic who left Ecuador, October 7, arriving in Panama four days later and was taken to the Ancon Hospital two days after his arrival. There is no probability of the disease spreading from this case.——Out of 75,000 rats killed and examined by the Seattle Health Department during the last fifteen months, only one was found to be infected with bubonic plague.——A case of yellow fever is reported from Honolulu. The patient was a Hawaiian and believed to have become infected from a Japanese steamer, which recently arrived in Honolulu from Central America.

Cooperation in the Administration of the Food and Drugs Act.—At the last meeting of the Association of State and National Food and Drug Departments at Duluth, Minn., the president, Lucius P. Brown, Nashville, Tenn., was instructed to appoint a committee to perfect plans for cooperation among state officials and national governments in the administration of the Food and Drugs Act. A committee was accordingly appointed, consisting of Dr. Samuel J. Crumbine, Topeka, Kan., for a five-year term; R. M. Allen, Kentucky, for a four-year term; R. V. Fitzrandolph, New Jersey, for a three-year term; L. Davies, Washington, for a two-year term, and Dr. A. N. Cook, South Dakota, for a one-year term. In accordance with the resolutions adopted at this convention that a committee be appointed to study the subject of cold storage and draft a measure incorporating in its provisions just and reasonable regulations for the operation of cold storage warehouses and the storage of foodstuffs therein, the president appointed a committee consisting of H. E. Barnard, Indianapolis; R. B. Fitzrandolph, Trenton, N. J.; Miss Mary E. Pennington, of the Department of Agriculture, Washington; M. E. Jaffa, Berkeley, Cal., and Hon. W. B. Barney, Des Moines, Ia. The officers have announced their desire to make the organization's influence felt as a factor in the enforcement of food laws and that they stand with Dr. Wiley for this platform.

LONDON LETTER

(From Our Regular Correspondent)

London, Oct. 28, 1911.

The Effects of the Great Railway Strike on the Public Health

The great railway strike which paralyzed traffic for some days on most of the lines in this country has been mentioned in a previous letter. Its detrimental effect on the public health of one of our greatest cities can now be estimated. Before the strike Liverpool, with an estimated population of 747,000, showed in recent years, in consequence of improved sanitation, great improvement in the death-rate from summer diarrhea in infants. During the past summer the rate has been extraordinarily low. During the five years, 1906-10, the average temperature in July was 58.9 F.; the average deaths from diarrhea in the four weeks of the month, 4, 6, 9 and 11, and the general death-rate for each week was 15 per thousand of the population. For the four weeks in August the average temperature was 59.5 F. and the deaths from diarrhea were 23, 34, 52 and 63, and the general death-rate 19. In the present year the average temperature was 64.1 F. and the average deaths from diarrhea 20, 23, 38 and 46, and the general death-rate ranged from 15 to 18. In August the average temperature was 68.8 F. and hardly any rain fell. This probably accounts for the fact that there were eighty-one deaths from diarrhea during the first week and that the general death-rate rose to 20. On August 5, strike troubles began and they reached their acme on the 17th. The sanitary service was interrupted, garbage accumulated, and the food-supply was seriously diminished. The consequences are shown by the statistics. For the second week in August there were 132 deaths from diarrhea and the general death-rate rose to 24 per thousand of the population. During the third week there were 159 deaths from diarrhea and the general death-rate was 27. With the restoration of the sanitary service the figures fell but remained high during September, when the deaths from diarrhea in the four weeks were 148, 130, 109 and 112. During the strike 300 butchers' shops were closed because they could not obtain meat and the interruption of the milk-supply had an immediate effect on infants. Even the hospitals suffered, although the strike committee endeavored to secure for them delivery of supplies.

The National Insurance Bill

The contest between the profession and the friendly societies on the national insurance bill continues. Mr. Lloyd-George, the chancellor of the exchequer, who has always shown great skill in assuaging quarrels and harmonizing conflicting interests, arranged a conference between six representatives of the British Medical Association and representatives of the friendly societies, at which he presided. The proceedings lasted two and one-half hours and an understanding was arrived at that they were to be kept private but the following has transpired: The societies objected to the fixing of the income limit by the health committee (described in a previous letter to The Journal). They asked for the right to form local medical associations, such as already exist in certain towns, and asked for an assurance that the medical profession would not endeavor to ostracize the doctors engaged by such associations. They also asked that insured persons should be entitled to have the personal attendance of the doctor desired and not be forced to accept the services of his assistant. The representatives of the British Medical Association stated that they had no authority to enter into an arrangement of any kind and that they could hold out no hopes of departure from the six cardinal points of policy declared (described previously in The Journal). Many members of the profession disapprove of taking part in the conference.

The Medical Equipment of Merchant Ships

A committee appointed by the board of trade, at the request of the General Shipowners' Society of London to consider the medical scales for merchant ships, has recommended four revised scales in place of those now in use. For ships which will carry a medical officer, including emigrant ships, two scales are recommended—one for the North Atlantic, where voyages are short and the numbers of passengers and crew large; the other for ships with fewer passengers which go on longer voyages. For each of these classes a list of the necessary instruments, including a sterilizer large enough to take a long midwifery forceps, is given. A microscope and bacteriologic outfit, such as are required in the larger vessels of some foreign countries, have not been recommended. The instrument and appliances for clinical work have been modernized. The appointment of a second medical officer to ships carrying a crew and passengers amounting to 1,500 is recommended, as well as a dispenser. The other two scales are for vessels which do not carry a medical officer and for fishing boats. One scale applies to ships whose voyages ordinarily last more than five days; the other, named an emergency scale, is for vessels never more than five days away from harbor, and applies to all sea-going ships; but coasting craft, whose voyages last no more than twenty-four hours, may conform to the emergency scale or carry the ambulance hamper of the St. John Ambulance Association. Antidiphtheritic serum, sealed and dated, is to be carried by all emigrant ships. The need for separate and reserved accommodation in cargo vessels for men who may become ill or injured is pointed out.

PARIS LETTER

(From Our Regular Correspondent)

Paris, Oct. 20,1911.

Dedication of a Monument to Michael Servetus

A monument, the third in France, was dedicated on October 15, to the memory of Michael Servetus at Vienne, department of l'Isère. Servetus is shown at the stake in the midst of flames, chained to a stone, his book bound to his side. In this book entitled, *Christianismi restitutio*, Servetus described for the first time the lesser circulation of the blood. Dr. Charles Richet, professor of physiology at the Faculté de médecine de Paris, who represented the University of Paris at the ceremony, said that the divination of the pulmonary circulation by Servetus, who, unlike Harvey, had done no vivisection, and who, unlike Vesalius, had done no dissection, was unparalleled —almost a miracle. The contemporaries of Servetus did not understand him and his discovery remained unknown. Seventy-five years had to pass before Harvey gave it a rigorous demonstration and forced recognition.

The Catastrophe of the "Liberté" and Microbes

The causes of the terrible catastrophe which destroyed the "Liberté," one of the finest vessels of our navy, are not yet established. Among the opinions of various specialists it is interesting to mention one, according to which the gun-cotton, technically known as powder B, should be considered, not only from the chemical but from the microbiologic point of view. For the chemist, the nitrification of cotton consists in making it an explosive; for the microbiologist, it is sterilizing it. If the nitrification of the cotton is incomplete, this is unimportant from the chemist's point of view, for the explosive still exists, while the microbiologist sees in the parts not nitrified a developing culture of microbes. In fact, powder B does not preserve its qualities indefinitely; it grows old; its homogenous and translucent aspect is darkened by spots which become concave and finally give forth oily exudations. These are the manifestations of the activity of certain anaerobic microbes which produce a series of gaseous bodies whose presence in air-tight receptacles may finally cause the explosion of the powder.

Sterilization of Water by Ultraviolet Rays

Drinking-water for Paris is ordinarily supplied from four derivations of spring-water, which are supplemented, when necessary, by filtered river-water. Lately the filtered waters have been treated sometimes by ozone, sometimes by ultraviolet rays. These experiments permit a comparison of the two procedures. The bactericidal action of ultraviolet rays is very powerful. To separate the ultraviolet rays from the red, green and yellow ones, the mercury-vapor lamp in transparent quartz, intended for illumination, was employed. The system devised by MM. Victor Henri, Max de Recklinghausen and André Helbronner is remarkably simple, requiring no complicated machinery. A slight electric current accomplishes the work, which is hygienically thorough. If the electric current is accidentally interrupted, an automatic sluice opens the conduit and empties the water which has not undergone sterilizing action. The operation of this apparatus is economical, as was shown in the results of a competition held last year by the city of Marseilles.

Death of M. Alfred Binet

Psychologic science has just experienced a great loss in the person of M. Alfred Binet, *docteur ès sciences*, director of the laboratories of physiologic psychology at the Hautes Etudes à la Sorbonne, who has died, aged 54. He was the author of numerous works on psychology, including "Alterations of the Personality," "The Soul and the Body," "The Revelations of Handwriting," etc. Binet gave this science a direction altogether personal and original with himself. He founded the *Année psychologique*. He took especial interest in pedagogical questions and recently published a book entitled, "Modern Ideas in Regard to Children." He was the president of the Société pour l'étude psychologique de l'enfant.

The Assassin of Dr. Guinard

Herrero, the assassin of Dr. Guinard, committed suicide recently in prison. He had previously made two unsuccessful attempts at suicide.

Death of Prof. Antoine Blatin

Dr. Antoine Blatin, former professor of physiology at the Ecole de médecine de Clermont, has just died, aged 72.

BERLIN LETTER

(From Our Regular Correspondent)

Berlin, Oct. 19, 1911.

Personal

The Breslau anatomist, Professor Hasse, celebrated his 70th birthday, October 17. He has been regular professor in Breslau since 1873.

Professor M. Hahn of Munich has received a call to Königsberg as director of the hygienic institute.

Professor Kehrer of Bern, the son of the well-known gynecologist of Heidelberg, has been called to the directorship of the gynecologic clinic at Dresden, as successor of Professor Leopold. As Kehrer's successor there have been proposed Professor Baisch of Munich and Professor H. W. Freund of Strasburg.

Foundation for the German Society for the Advancement of Science

The Gesellschaft deutscher Naturforscher und Aerzte has just received an endowment, the Adelaide Bleichroeder fund of $25,000 (100,000 marks). The foundation is for the assistance of scientific work in the field of medicine, including the ancillary sciences. As the entire fund is to be distributed in thirty years, an annual sum of about $1,500 (6,000 marks) will be available. Among the competitors, those who have no official posts or are not connected with well endowed institutions shall be preferred.

German Institute for Foreigners

Following the suggestion of the deceased Althoff, a German institution for foreigners, like the institution in Göttingen which I have previously told you about, has been founded in Berlin, with means provided by privy councilor Böttinger. The purpose of the institution is to furnish educated foreigners who are residing temporarily in Berlin an intellectual headquarters for their studies and an introduction to the study of German civilization. In addition courses in speaking German and introductory lectures on German literature and art have been provided. Visits to the art treasures of Berlin and excursions to other seats of culture in Germany will be made. The bureau is located at 8 University Street, Berlin, and is open to foreigners daily from 2 to 4 p. m.

Collective Investigation of Round Ulcer of the Stomach

A number of Bavarian university teachers and physicians have instituted a collective investigation of the etiology and clinical course of ulcer of the stomach. The request is made that material from operations and necropsies be sent to the pathologic institute in Erlangen with a filled out question blank giving the clinical data of the operated cases of those controlled by section. The anatomic material is to be examined by Professors Hauser and Merckel, the clinical by v. Angerer, v. Bauer, Borst, Crämer, Enderlen, Graser, v. Leube, F. V. Müller and Penzoldt. Question blanks and further information can be obtained from Prof. Hauser of Erlangen, Prof. N. Merckel of Erlangen and court councilor (Hofrat) Cramer of Munich.

Spitting in Railroad Cars

While spitting is forbidden in the street cars of Berlin and other places and in foreign railway cars, such a prohibition has not yet been made on the German railroads. At the request of the management of the railroads, the scientific deputation for medical affairs made an expert report regarding the necessity of such a prohibition. The results of the investigation undertaken by the former hygienist of Graz, Professor Prausnitz, and Petri, a member of the imperial health office, on the railway cars which run between Berlin and Meran and are patronized by *many consumptives, showed that there is no regular* or even frequent presence of tubercle bacilli, capable of causing infection, in the dust of railway cars. Furthermore the investigations of Flügge have shown that the danger from the inhalation of dried sputum is not very great, and is far less important than the danger from the so-called *droplet infection.* Still the scientific deputation holds that spitting on the floor and the possibility of soiling it in this way with tubercle bacilli should by all means be prevented. The instruction of the public by warning notices is thoroughly justified as the evil produced by spitting in a confined space is very great. It should also be required that the employees of the company enforce the regulations against travelers who transgress them. In this respect the measures in force in many localities, especially on foreign roads, leave much to be desired. For instance in the Italian railway cars the floor is soiled with spitting since expectoration has been prohibited as much as before the regulations against this were adopted.

VIENNA LETTER

(From Our Regular Correspondent)

Vienna, Oct. 24, 1911.

Opening of the Radium Institute of Joachimsthal

At Joachimsthal, a Bohemian mining place, the government has erected an institute which is to be devoted entirely to the use of radio-active substances for medical purposes. It is well known that the startling discoveries of Becquerel and Curie in Paris were made on uranium obtained from material found in the mines of Joachimsthal. Soon afterward exhaustive researches in the mother substance in Joachimsthal showed the water found in the mines to be the most radioactive natural water in the world. A private syndicate was soon organized for the purpose of exploiting this natural resource; but public opinion forced the government to assume control of the affair and to erect a *Curanstalt*, a therapeutic institution, accessible to all classes of the population. From the material obtained in these government mines—in old *days they yielded a fair amount of silver, too—a large quantity* of radium bromid could be manufactured, and in the institute all kinds of treatment by radio-active substances will be given. The building was recently opened; it contains radio-active baths, a large quantity of the radium salts, and will be open all the year round. *By pipes the water is drawn* into the baths directly from the bottom of the mines, and filtered in such a way that it does not lose anything of its activity. The institution is in charge of an expert medical radiologist from the Vienna University.

Turbulent Demonstrations Against Inadequate Institutes

The Anatomical Institute of Vienna was erected some twenty-five years ago in a street which at that time was in the suburbs; the building itself was estimated to accommodate some 200 students. During the last twenty-five years, however, the number of medical students has increased in such a degree, and the popularity of the professors of the institution has been so marked, that the lectures are exceptionally crowded, and the building is insufficient for the acommodation of the large number of students eager to gain the fundamental knowledge of our art. In the dissecting-room only 200 chairs are available, while more than 500 students are at work at the same time and not all of these can find place at the dissecting tables. Even the facilities for washing the hands are on a scale which would hardly have been accepted a quarter of a century ago. Ventilation is very bad, for, owing to the rapid development of the suburb, the building is now surrounded by other buildings, and the windows cannot be opened whenever it would be required. Therefore the indignation of the students and the teaching staff of the university was strong when; a few years ago, a demand for improvement of the conditions was frustrated by the government for lack of means. This year, at the opening of the winter term, the students at once started a turbulent demonstration and, assuring the professor, Dr. Tandler, that the riot was not directed against him, began to disturb the lectures to cause a "strike." The professor sympathized with the students, went with them to the rector of the university, and a deputation was sent to the minister of education in order to demand the funds necessary for the removal of the worst grievances. They were granted money for a sufficient number of chairs, tables, washing apparatus and wardrobes for the cloak-rooms. The chief source of discontent, however, is the site of the institution itself and this cannot be changed at present.

Marriages

Clara O. Dedrick, M.D., De Tour, Mich., and Mr. W. W. Dunham of Drummond, Mich., at Sault Ste. Marie, Mich., October 18.

Harry V. Thomas, M.D., Chillicothe, Ill., to Miss Jane Neff of Oklahoma City, Okla., at Kansas City, Mo., October 15.

Carlisle E. McKee, M.D., Braddock, Pa., to Miss Ethel Eleanor Sutmeyer of Wilkinsburg, Pa., October 19.

Henry Clarke Thacher, M.D., New York City, to Miss Ethel Anderson of Washington, D. C., October 21.

Andrew S. Reisor, Jr., M.D., Shreveport, La., to Mrs. Blanche Locke of DeQueen City, Ark., October 18.

Arthur H. Estabrook, M.D., Leicester, Mass., to Miss Jessie McCubbin, at Mt. Washington, Md., October 25.

John Douglas, M.D., New York City, to Mrs. Elizabeth Thayer Hoag of Washington, D. C., October 24.

Miller M. Harshbarger, M.D., St. *Anthony, Ida., to* Miss Grace Campbell of Valier, Mont., October 18.

Emil C. Robitshek, M.D., Minneapolis, Minn., to Miss Leonora Millhauser of Chicago, November 1.

Sparrell S. Gale, M.D., Roanoke, Va., to Miss Gretchen Harding of Canon City, Colo., October 17.

Howard H. Shepler, M.D., Philadelphia, to Miss Ethel F. Heyser of Hagerstown, Md., October 24.

Alexander B. Kalbaugh, M.D., to Miss Rosalie Morrison, both of Westernport, Md., October 12.

Joseph W. Preisinger, M.D., Renville, Minn., to Miss Ella Wigdahl of Crooks, Minn., October 8.

Woodson J. Moss, M.D., to Mrs. Luella Wilcox St. Clair, *both of Columbia, Mo., October 22.*

W. L. Breyfogle, M.D., to Mrs. Ella Naomi Pierce, both of Lake George, N. Y., October 14.

Oscar Paul Chester, M.D., to Miss Florence Cathryn Griffin, both of Chicago, October 18.

William B. Kunze, M.D., to Miss Eugenia Eimer, both of Belleville, Ill., October 18.

Roy F. Bellaire, M.D., Le Mars, Ia., to Miss Mary Ramsay, of St. Louis, recently.

Deaths

Agrippa Nelson Bell, M.D. Jefferson Medical College, 1842; founder of *The Sanitarian* in 1873 and its editor until 1904; a member of the American Public Health Association and American Climatological Association; president of the American Congress on Tuberculosis, 1901-2, and honorary president of the International Congress of Tuberculosis in 1904; passed assistant surgeon U. S. Navy from 1847 to 1855 with service during the Mexican War; a medical officer of the navy during the Civil War; superintendent of the Floating Hospital for Yellow Fever Patients, New York City, 1861; from 1870 to 1875 inspector for quarantines for the National Board of Health; a member of the National Quarantine Convention from 1857 to 1860; commissioner of quarantine of New York from 1870 to 1873; for twenty-one years visiting physician to the Brooklyn Hospital; died at his home in Brooklyn, October 15, from senile debility, aged 91.

George Frederick Jelly, M.D. Harvard Medical School, 1868; a member of the American Medical Association and American Medico-Psychological Association; a member of the Massachusetts State Board of Insanity and for many years chief examiner of the insane for the city of Boston; from 1869 to 1871 assistant city physician at the McLean Hospital, Waverly, and from 1871 to 1879 superintendent of that institution; first chairman of the Massachusetts State Board of Insanity; whose services were extensively sought as a consultant and medical expert in nervous and mental diseases; consulting physician to the New England Hospital for Women and Children; died at his home in Wakefield, October 24, from nervous breakdown, aged 69.

John W. Warner, M.D. Albany (N. Y.) Medical College, 1847; a member of the Medical Society of the State of New York; for more than fifty years a practitioner of New York City, but since 1898 a resident of Saratoga Springs; died at his home in that place, October 23, aged 88.

Wooten Moore Wilkerson, M.D. University of Virginia, Charlottesville, 1879; New York University, New York City, 1880; a member of the American Medical Association; once president of the Medical Association of the State of Alabama, and at the time of his death chairman of the committee of health for Montgomery County; visiting physician to St. Margaret's Hospital, Montgomery; a trustee of the Bryce Insane Hospital and president of the Montgomery County Board of Health; died at his home in Montgomery, October 22, from heart disease, aged 53.

Harvey E. Williamson, M.D. Keokuk (Ia.) Medical College, 1894; a member of the Kansas Medical Society; local surgeon of the Frisco System and Missouri, Kansas and Texas Railway, at Olathe; surgeon to the deaf and dumb institution of Kansas, Olathe; who five years ago had the misfortune to be thrown from, and run over by a street car in Kansas City, the injury necessitating the amputating of both feet; died at the home of his parents in Clarinda, Ia., October 23, aged 42.

John Reese Uhler, M.D. University of Maryland, Baltimore, 1861; one of the founders of Baltimore Medical College and for several years professor of chemistry and surgery in that institution; surgeon of the Fifth Maryland Volunteer Infantry during the Civil War; one of the founders and once president of the Baltimore Medical Association and one of the founders of the Clinical Society of Baltimore; died at his home in Baltimore, October 9, from nephritis, aged 72.

Samuel Alexander Helfer, M.D. New York University, New York City, 1875; a member of the Medical Society of New Jersey; in 1895 city physician and a member of the board of health of Hoboken; for many years physician to the steamship companies whose docks are in Hoboken; senior member of the board of trustees of the Hoboken Board of Trade; died at his home, October 24, from diabetes, aged 67

Mathias William Dvorak, M.D. College of Physicians and Surgeons, Chicago, 1903; a member of the State Medical Society of Wisconsin and secretary for two terms and up to the time of his death of the La Crosse County Medical Society; a beloved and highly respected young physician of La Crosse; died in St. Francis Hospital in that city, October 19, from typhoid fever, aged 31.

W. R. Hurst, M.D. Western Reserve University, Cleveland, 1862; a member of the Ohio State Medical Association and for nearly fifty years a practitioner of Piketon; died in the Protestant Hospital, Columbus, October 24, two days after a surgical operation, aged 74.

Nelson E. Bradley, M.D. Medical College of Ohio, Cincinnati, 1882; for many years a practitioner of Felicity; formerly a member of the local U. S. pension examining board; died at his home near Batavia, O., October 22, from heart disease, aged 53.

James H. Gaston, M.D. Miami Medical College, Cincinnati, 1872; a veteran of the Civil War; from 1888 to 1890 treasurer of Monroe County, Ind.; died at his home in Axtell, Kan., October 11, from heart disease, aged 67.

William A. H. Jenner, M.D. University of Munich, Germany, 1872; a member of the Washington State Medical Association, and a pioneer practitioner of Seattle; died recently and was buried October 15, aged 67.

Willard B. Croft, M.D. Cleveland University of Medicine and Surgery, 1882; a specialist on diseases of the eye, ear, nose and throat, of Medina, O.; died at his home, August 26, from leptomeningitis, aged 55.

Charles A. Butner, M.D. University of Louisville (Ky.), 1885; a member of the Medical Association of Georgia; died suddenly at his home in Jackson, October 16, from acute gastritis, aged 52.

William Curry, M.D. Jefferson Medical College, 1895; a member of the Butler County (Pa.) Medical Society; died in Butler, Pa., October 11, after an operation for right pyonephrosis, aged 40.

William Graham Armstrong, M.D. Medical College of Ohio, Cincinnati, 1882; formerly of Flemingsburg, Ky.; died at his home in Lantana, Fla., March 4, from pulmonary tuberculosis, aged 50.

Forrest B. Seymour, M.D. Medical College of Ohio, Cincinnati, 1889; a member of the State Medical Association of Texas; died at his home in Beeville, October 7, from nephritis, aged 45.

Peter Fehr, M.D. Cleveland College of Physicians and Surgeons, 1896; a member of the Ohio State Medical Association; died at his home in Akron, October 21, from tuberculosis, aged 44.

George Joshua Atkins (license, North Carolina, 1894); of Newell; a member of the Medical Society of the State of North Carolina; died in Charlotte, N. C., July 18, from uremia, aged 57.

John Jessiah Bilheimer, M.D. Jefferson Medical College, 1891; formerly a member of the American Medical Association; died suddenly at his home in Priceburg, Pa., October 19, aged 42.

Henry George, M.D. Detroit College of Medicine, 1887; physician of Wayne County in 1896 and 1897; died at his home in Detroit, October 15, from cerebral hemorrhage, aged 51.

Charles Christian Fredigke, M.D. College of Physicians and Surgeons, Chicago, 1887; of Chicago; died at the Alexian Brothers' Hospital in that city, October 21, aged 72.

Winfield Taylor Browning, M.D. Bellevue Hospital Medical College, 1873; for several terms burgess of Orbisonia, Pa.; died at his home, October 16, from diabetes, aged 63.

Theodore Lavilvarasse, M.D. St. Louis College of Physicians and Surgeons, 1896; of Boston; died in the Boston City Hospital, Oct. 25, 1910, from pulmonary tuberculosis.

Luther Leonidas White (license, Randolph County, Ala., 1879); of Roanoke, Ala.; died in Springfield, Ala., April 22, 1910, from angina pectoris, aged 58.

Harman Yerkes Longacre, M.D. University of Michigan, Ann Arbor, 1876; died at his home in St. Charles, Ill., October 18, from hemorrhage, aged 56.

I. M. Hightower, M.D. Georgia College of Eclectic Medicine and Surgery, Atlanta, 1889; died at his home in Cartersville, Ga., October 11, aged 47.

Everett F. Harrington, M.D. Lincoln (Neb.) Medical College, 1902; died at his home in Watertown, S. Dak., October 6, from heart disease, aged 50.

William L. Gibson (license, Arkansas, 1903); a practitioner of Craighead, Ark., since 1882; died at his home in Greenboro, October 13, aged 55.

Robert Lee Caldwell, M.D. Washington University, St. Louis, 1899; died at his home in Grove, Okla., February 21, from septicemia, aged 44.

Joseph Werthner, M.D. Miami Medical College, Cincinnati, 1882; of Burdick, Kan.; formerly of Dayton, O.; died in Elmo, Kan., October 20.

William G. Johnson, M.D. University of Pennsylvania, Philadelphia, 1870; died at his home in Farmington, N. C., October 14, aged 67.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

OZONIZED TESTIMONIALS

Obtaining Clinical Reports on "Oxyoline Therapy"

A few weeks ago we called attention to the method adopted by the proprietor of a medical journal in obtaining testimonials favorable to products advertised in his publication. As will be remembered, the method consisted in sending out letters to his subscribers telling them how highly he, the proprietor, valued the products and asking physicians if they would not "cooperate" by writing their opinion of the same products. A crude modification of this method of obtaining testimony favorable to products advertised in medical journals has recently been called to our attention.

The *American Journal of Physiologic Therapeutics* is the somewhat imposing title of a publication that is said to be "a practical journal of progress in non-medicinal therapy." Incidentally, the advertising pages of this non-medicinal publication are devoted largely to medicinal products! The proprietor of this journal is also the proprietor of another journal which is said to be "a journal of commercial medicine." Both of these journals carry advertisements—large ones—of a device known as the "Oxyoline Apparatus," which is supposed to depend for its action mainly on its ability to produce ozone. Moreover, the proprietor of these journals is understood to be the advertising agent for the concern that exploits this "apparatus!" What the Oxyoline machine will not do in the way of abolishing or preventing disease is negligible—if the claims of the promoters are to be believed, which they are not. So much by way of explanation.

Three weeks ago,[1] in commenting on "The Alleged Hygienic Value of Ozone," we seem to have hurt "business"—advertising and other. At any rate, the following letter from the publisher and editor of the *American Journal of Physiologic Therapeutics* has been received by physicians:

> October 27, 1911.
>
> *My dear Doctor:*—I have just read a most remarkable editorial in The Journal A. M. A., Oct. 21, 1911, page 1370, entitled "The Alleged Hygienic Value of Ozone."
>
> Does your clinical experience prove this or not? I am tempted to make a "big stir" regarding this wholly unwarranted attack on Ozone, and I am very anxious to produce an interesting symposium on Ozone in the next issue of *Physiologic Therapeutics*. Will you not send me four or five hundred words for publication, giving your personal opinion regarding this matter as based on your own clinical experience?
>
> If, in your reading, you have found any articles on this subject or any clippings relating to Ozone or Oxyoline therapy, and you can send them along, I will be very grateful indeed, and in remuneration for your cooperation will be pleased to give you a one year's subscription to *Physiologic Therapeutics* or a five years' subscription to *Successful Medicine*.
>
> I await your prompt reply, and, to facilitate this, a self-addressed, stamped envelope is enclosed.
>
> Very cordially yours,
> Physiologic Therapeutics
> *Henry R. Harrower*,
> Managing Editor.

The *quid pro quo* is perfectly evident. Stated a little more baldly this letter seems to mean: "Send us a testimonial on the 'Oxyoline Apparatus' and we will give you a year's subsubscription to our journal." The arrangement must be an eminently satisfactory one. The advertiser is "boosted"; the advertising agent—the editor and publisher in this instance—gets more business; the original article department of the journal is cheaply and easily filled; the subscription list is boomed with what the postal authorities we presume will consider *bona fide* subscribers, and altogether it is a very admirable arrangement—for everyone except the public and the medical profession.

Those physicians who read Mr. Irwin's admirable series of articles on "The American Newspaper" doubtless had their indignation aroused when they learned that certain large metropolitan dailies would have their dramatic critics write fulsome puffs of current theatrical attractions on the tacit understanding that the theatrical company would purchase large advertising space. And yet this exhibition of venality only affected the public's pocketbook; it in no way jeopardized its health. Of course, such dramatic criticism is a farce; but what about "scientific criticism" of therapeutic agents that is purchased at the price of a subscription to a medical journal by those who are financially interested in the exploitation of such agents?

CINERARIA MARITIMA

Report of the Council on Pharmacy and Chemistry

Occasional inquiries in regard to the therapeutic value of *Cineraria maritima* caused the Council to consider the drug with reference to its fitness for inclusion in N. N. R. among non-official, non-proprietary remedies. The following report, having been submitted to the Council by a subcommittee, was adopted and its publication authorized.

W. A. Puckner, Secretary.

To the Council:—The juice of a plant referred to as *Cineraria maritima* was at one time supposed to be of value in the treatment of cataract and certain other affections of the eye. No scientific evidence is available to show that the drug is therapeutically active, and its value is no doubt correctly estimated by Dr. Casey Wood, who ("Ophthalmic Therapeutics," p. 446; Cleveland Press, Chicago, 1909) says:

> "Still, a few respectable names have been associated with its [*Cineraria maritima*] employment in that capacity and it only remains to be said that the instillation into the conjunctival sac of a preparation of this or any other member of the *Senecio* family has about as much effect on the resolution or dispersal of opacities due to organic changes in the lens as pouring the same down the back of the patient's neck!"

The plant from which *Cineraria maritima* juice is claimed to be prepared is commonly referred to in literature as *Cineraria maritima*, but is more correctly described as *Senecio cineraria*, D. C.

It may be considered a matter of indifference whether a remedy like this be advertised for the treatment of such disease as cataract, providing its application could do no harm, but it must be remembered that it is recommended also for other diseases of the eye in which its use, by postponing efficient treatment, would be the means of serious damage or even loss of vision.

Since there is no evidence to show that this drug is of any therapeutic value, it is recommended that it be not admitted to the list of non-official, non-proprietary remedies in N. N. R., and that the Council formally express its opinion that the drug, as judged by the evidence which is available, is without value in the treatment of cataract or similar diseases of the eye.

Editorial Comment: *Cineraria maritima* would long since have been relegated to the limbo of discarded and discredited drugs had it not been given a semiproprietary character by a St. Louis nostrum house—the Walker Pharmacal Company—which, like the Manola Chemical Company, is, we understand, practically a subsidiary concern of the Luyties Homeopathic Pharmacy Company. The Walker concern exploits this drug under the name Succus Cineraria Maritima (Walker). Its method of exploitation consists in publishing testimonials, which it dignifies with the name "clinical reports," from men whom it designates as "representative physicians." As indicative of what constitutes representative physicians, we find that of the seven testimonials given in their pamphlet the names of three of the signers are not to be found in any medical directory.

The exploitation of Succus Cineraria Maritima (Walker) is the oft-repeated story of the resurrection of discarded and worthless drugs for the purpose of creating proprietorship in a nostrum. *Cineraria maritima* is worthless; its therapeutic value is *nil*. By the prodigal use of printers' ink, the medical profession—and through it the public—has been humbugged into believing that it possesses curative value.

Correspondence

Leishmaniosis in China

To the Editor:—The Journal, August 12, contained an editorial on "Infantile Splenic Anemia and Kala-Azar" which is of considerable interest to me as I live in a district where leishmaniosis is common, though the positive diagnosis made by finding the parasite is comparatively recent. I am writing you because your suggestion that cases may possibly occur in America among immigrants is entirely reasonable, and our experiences may be of some use to men who are on the lookout for it.

The microscopic diagnosis is much more troublesome than that of malaria because the parasite is not always found in the circulating blood or, if it should be present, it is in such scanty numbers that the search is exceedingly tedious and it is practically useless to depend on it as a means of diagnosis. It is much more easily found in the smears made from splenic puncture, but the spleen is so friable that a number of fatal hemorrhages are reported even when great care was used, and some of the best authorities discourage the use of the method because of this danger. Puncture of the liver is less dangerous but it is also a less certain source of the parasite and long search may be necessary to find it. Even splenic punctures sometimes require a considerable time before the search is successful. The organism is said to be found in the fluid of fly-blisters and croton-oil vesicles, but not regularly, and we have failed to demonstrate *Leishmania* in the two or three cases in which this method has been tried.

---

[1] The Journal A. M. A., Oct. 21, 1911, p. 1370.

During the last few months I have used successfully a plan which I have not seen described elsewhere. One of the superficial lymph-nodes, either the postcervical or inguinal, is excised under local anesthesia of quinin and urea hydrochlorid, and smears are made from its cut surface. In seven successive cases the parasite was found readily, six of the seven showing it in less than five minutes' search, the other requiring twenty minutes. From this brief experience it would seem probable that the method is quicker, more certain and less dangerous than those previously practiced.

The smears are best stained by Wright's, Leishman's or Giemsa's methods. They stain less readily than do malaria organisms in our experience, requiring longer staining; we have had good results with Leishman's stain by using the pure staining fluid for five minutes, adding the distilled water for ten or fifteen minutes and then clearing by distilled water alone for two minutes. The methyl alcohol evaporates quickly during the first step, causing precipitates and a dirty slide; this may be avoided by covering the slide with a Petri dish.

The parasites are harder to recognize than malarial organisms, as they are smaller and contain no pigment, and it is sometimes not easy to decide whether a given body is the parasite or merely detritus staining in a similar manner. Those not familiar with them would do well to compare their slides with the beautiful plate in the frontispiece of Manson's "Tropical Diseases," fourth edition.

The evidence in favor of the bedbug as a possible intermediate host not only consists in the fact that the parasite multiplies and shows the same developmental forms in the bug as are found in cultures, but also in the success that Rogers has had in preventing the disease by prophylactic measure directed against bedbugs (Rogers: "Fevers of the Tropics," p. 93.)

The two diseases to which you refer in the title of your editorial, if not absolutely identical, would seem at least very closely related. The practical identity of the symptoms and the pathology, and of the morphology of the parasite, furnishes a strong presumption in favor of the identity of the diseases. The failure which you report to culture the parasite of kala-azar continuously and the failure to inoculate dogs may be due to some slight difference in technic. Although there is a difference in the age of the individuals attacked, this is less than would appear, for Rogers (in "Fevers of the Tropics," p. 50) reports that in Assam 50 per cent. of the patients are under 20 years, and in Sylkhet 70 per cent. are under 20. There seems to be a gradual gradation in the average age of the patients in different places. Our patients are almost all children, but older than those reported by Nicolle from Tunis, being midway between them and Rogers' Indian patients. Furthermore, it is apparently true that adults may be attacked by the Mediterranean type of leishmaniosis, for two cases, one patient 18 years old and the other 30, are reported from Athens (The Journal, May 13, 1911, p. 1428).

Samuel Cochran, Hope Hospital,
Hwaiyuan Anhwei, China.

Queries and Minor Notes

Anonymous Communications will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

BREEDING AND CARE OF GUINEA-PIGS AND RABBITS

To the Editor:—Have you any information relative to the care of laboratory animals, such as guinea-pigs and rabbits, their food, habits of life, diseases? I am interested more especially in the last, as our animals are not doing well. Can you give me a reference list where I can obtain this information? The ordinary books on zoology do not contain much on the care of sick guinea-pigs.

W. J. Doyle, St. Louis.

Answer.—The above letter was referred to the director of the Hygienic Laboratory of the U. S. Public Health and Marine-Hospital Service, who replies:

"At the Hygienic Laboratory we raise between 4,000 and 6,000 guinea-pigs every year and our success has been unusually satisfactory.

"First of all, a warm, sunny building should be provided, one that may be heated during cold weather. It has been our experience that if the temperature remains below 65 F. for any length of time the breeding is very much lessened and, moreover, many of the animals die. We keep four female breeders and one male in each cage. The male is allowed to remain in the cage all the time. The young are not removed from the cage until about four weeks old, when they are removed, each sex being placed in separate runs. It is important that the cages be cleaned out at least three times a week.

"The guinea-pigs are fed each day with a mixture of about equal parts of bran and oats and some green food—in the winter this is usually cabbage or carrots, during the summer alfalfa, green corn-stalks or clover. Each cage is provided with water and a small lump of rock salt. For bedding we use a small amount of cut hay; in addition to its use as bedding, the animals are fond of it. It is important that healthy stock be used for breeding purposes and that inbreeding be prevented as much as possible.

"The only diseases to which we have found our guinea-pigs liable are a streptococcic adenitis, which has given us some trouble at times; and a few years ago we lost a considerable number from a streptococcic pneumonia. A few female guinea-pigs die of postpartum infection with an organism of the hog-cholera group. Other than the above they suffer with practically no diseases. When given proper attention, their breeding is a simple and profitable proposition.

"We have raised but few rabbits at the laboratory, as we have found it cheaper to buy them on account of the cost and difficulty of raising them. They are subject to many more diseases, especially the young rabbits, than are guinea-pigs, the most important of these being coccidiosis of the intestine and liver, and pneumonia.

"The food for rabbits is the same as that given above for guinea-pigs. Both species of animals do better when kept in a warm building. We do not allow any of our animals to run outdoors. A cement floor is inadvisable."

MORTON'S FLUID

To the Editor:—Please give me the formula for Morton's fluid and state its use.

Z. Slavinski, M.D., Warsaw, Poland, Russia.

Answer.—Morton's fluid has the following formula:

℞	Gm. or c.c.	
Iodin	0|6	gr. 10
Potassium iodid	2	gr. 30
Glycerin	30	℥ 1

It was formerly employed by injection for the cure of spinal meningocele. The sac being cleaned, the child was placed on its side and a little chloroform was given. A fine trocar was plunged obliquely in at the side through sound skin, little or no fluid being drawn off, and 1 dram of Morton's fluid injected. The trocar was withdrawn and the puncture sealed with a bit of gauze and iodoform collodion.

SANITARIUM SYNONYMOUS WITH SANATORIUM

To the Editor:—Please give the proper use of the words "sanitarium" and "sanatorium" as in naming an institution for the care of the sick.

F. J. W.

Answer.—Use "sanatorium." Some make a distinction in the meaning of these two words, defining "sanitarium" as a resort for the preservation of health, and "sanatorium" as an institution for the treatment of chronic diseases, such as tuberculosis and nervous disorders. The two words are properly synonymous. The "Century" and "Murray" (the Oxford dictionary which is the court of last appeal among scholars and philologists) give "sanatorium" as the correct form; both, however, include "sanitarium" but refer to "sanatorium" for definition. "Sanatorium" is the neuter of the late Latin word *sanatorius*, meaning health-giving.

IRON SOLUTION GIVEN IN CAPSULES TO PROTECT TEETH

To the Editor:—I have noted lately in some of the medical journals discussions as to the best way to protect the teeth when giving iron. For some time now I have ordered a dropper and empty capsules to accompany the tincture, with directions to put the prescribed number of drops of the tincture in the capsule, to put on the cap and take, followed by water. In this way the teeth are not affected.

J. Lloyd Woodruff, Salt Lake City.

The Public Service

Medical Department, U. S. Army

Changes during the week ended Nov. 4, 1911.

Lake, G. B., lieut., ordered to Jefferson Barracks, Mo., during the absence of Capt. R. W. Bryan. Arrived Oct. 28, 1911.

Siler, J F., captain, granted leave of absence for one month and twelve days.

Webber, H. A., major, granted leave of absence for one month on relief from Fort Niagara.

Napier, E. L., lieut., granted leave of absence for one month, about December 1.

Smith, A. M., lieut.-col., granted leave of absence for one month, about November 5, with permission to apply for one month.

Mason, G. L., dental surgeon, October 30, left Fort Omaha, Neb., for Fort Crook, Neb.

Kean, J. R., lieut.-col., ordered to Havana, Cuba, to represent the Medical Department of the Army at the meeting of the American Public Health Association, Dec. 4 to 9, 1911.

The following named officers are detailed to represent the Medical Department of the Army at the Clinical Congress of Surgeons of North America, to be held at Philadelphia, Nov. 6 to 17, 1911: Reynolds, F. P., major; Persons, E. E., major; Reynolds, G. R., major; Williams, A. W., captain.

Borden, W. B., lieut., granted leave of absence for two months.

Fish, O. C., lieut., sick leave of absence extended one month.

Buchsbaum, Maurice, M.R.C., November 1, relieved from treatment at army general hospital, San Francisco, and ordered to his home; granted two months and three days leave of absence.

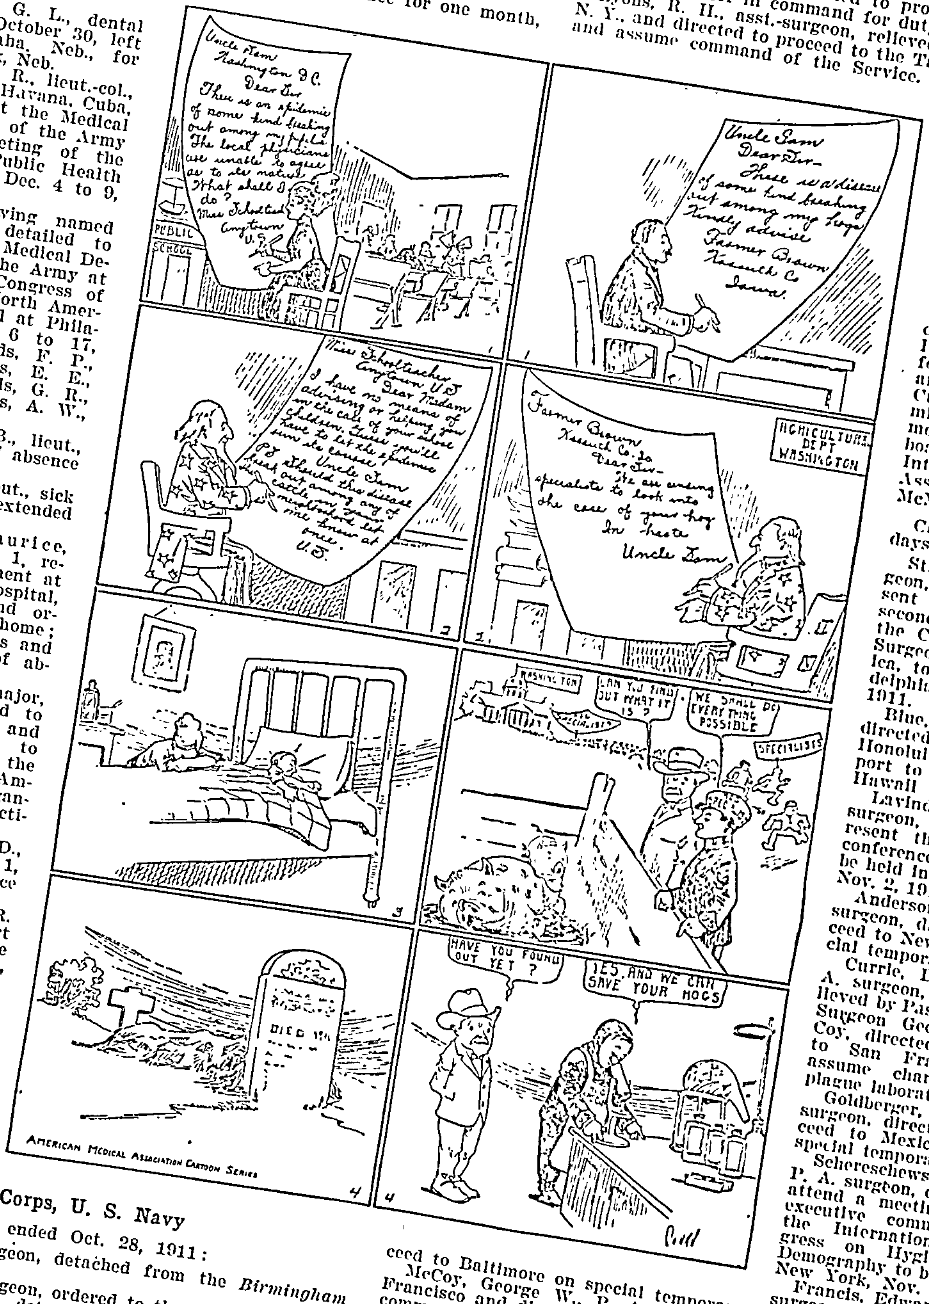
Patterson, R. U., major, November 1, ordered to proceed to Hartford and New Haven, Conn., to give instructions to the Field Hospital and Ambulance Company, Organized Militia of Connecticut.

Bloombergh, H. D., major, November 1, granted leave of absence for two months.

Whitney, W. W., M.R.C., October 30, left Fort McPherson, Ga., en route to Fort Moultrie, S. C., on detached duty.

Clark, John A., capt., November 1, relieved from duty at Plattsburg Barracks and ordered to Fort Wadsworth, N. Y.

Humphreys, Harry G., captain, November 1, relieved from duty at Fort Wadsworth and ordered to Plattsburg Barracks, N. Y.



Uncle Sam Washington D C.
Dear Sir
There is an epidemic of some kind breaking out among my pupils The local physicians are unable to agree as to its nature. What shall I do?
Miss Schoolteacher Anytown U.S.

Medical Corps, U. S. Navy

Changes during the week ended Oct. 28, 1911:

Brooks, F. H., P. A. surgeon, detached from the *Birmingham* and ordered to the *Marietta.*

Hough, F. P. W., P. A. surgeon, ordered to the *Franklin.*

Blackwood, N. J., surgeon, detached from the naval hospital, New York, and ordered to command the naval hospital, Canacao, P. I.

Changes during the week ended Nov. 4, 1911.

Giltner, H. A., P. A. surgeon, commissioned passed assistant surgeon from Sept. 10, 1911.

McLean, N. T., P. A. surgeon, ordered to duty at the naval hospital, New York.

Mackenzie, E. G., P. A. surgeon, detached from the naval hospital, New York, and granted sick leave for six months.

Jones, E. L., P. A. surgeon, ordered to duty at the naval hospital, Canacao, P. I.

U. S. Public Health and Marine-Hospital Service

Changes for the fourteen days ended Oct. 25, 1911:

Carter, H. R., surgeon, granted two months' leave of absence from Sept. 14, 1911, on account of sickness.

White J. H., surgeon, granted one month's leave of absence from Oct. 12, 1911, on account of sickness.

Gwyn, M. K., P. A. surgeon, relieved from duty at Baltimore, and directed to proceed to Ellis Island, N. Y., and report to Chief Medical Officer for duty.

Robertson, H. McG., P. A. surgeon, on being relieved by Assistant Surgeon R. H. Lyon, directed to proceed to Baltimore and report to medical officer in command for duty and assignment to quarters.

Lyons, R. H., asst.-surgeon, relieved from duty at Ellis Island, N. Y., and directed to proceed to the Tampa Bay Quarantine Station and assume command of the Service.

Kearney, R. A., asst. surgeon, relieved from duty on revenue cutter *Manning* and directed to rejoin station at San Francisco.

Schwartz, Louis, asst. surgeon, relieved from duty on revenue cutter *Tahoma* and directed to report to the medical officer in charge at Seattle for temporary duty.

Board of medical officers convened to meet at Baltimore, Oct. 25, 1911, for the examination of an officer of the Revenue-Cutter Service, to determine his fitness for promotion. Detail for the board: Surgeon W. P. McIntosh, chairman; Passed Assistant Surgeon John McMullen, recorder.

Changes for the seven days ended Nov. 1, 1911.

Stimpson, W. G., surgeon, detailed to represent the Service at the second annual meeting of the Clinical Congress of Surgeons of North America, to be held at Philadelphia, Nov. 7 to 16, 1911.

Blue, Rupert, surgeon, directed to proceed to Honolulu, T. H., and report to the Governor of Hawaii for special duty.

Lavinder, C. H., P. A. surgeon, detailed to represent the Service at a conference on pellagra to be held in Columbia, S. C., Nov. 2, 1911.

Anderson, J. F., P. A. surgeon, directed to proceed to New York on special temporary duty.

Currie, Donald H., P. A. surgeon, on being relieved by Passed Assistant Surgeon George W. McCoy, directed to proceed to San Francisco and assume charge of the plague laboratory.

Goldberger, J., P. A. surgeon, directed to proceed to Mexico City on special temporary duty.

Schereschewsky, J. W., P. A. surgeon, directed to attend a meeting of the executive committee of the International Congress on Hygiene and Demography to be held in New York, Nov. 4, 1911.

Francis, Edward, P. A. surgeon, directed to proceed to Baltimore on special temporary duty.

McCoy, George W., P. A. surgeon, relieved from duty in San Francisco and directed to proceed to Honolulu, T. H., and assume command of the leprosy investigation station.

Rucker, W. C., P. A. usrgeon, directed to proceed to San Francisco and report to Surgeon Rupert Blue for temporary duty.

Medicine and Nature.—Fernel, the great medical teacher, says: "Medicine, the eye always fixed on Nature, and, as it were, made in her image and resemblance, takes her law for guide, studying and bending every effort to imitate her, in order to preserve man's health constant and exempt from maladies, to restore and reestablish it when it totters and becomes deranged, finally to prolong life itself sound and safe as long as it is possible."

POSTGRADUATE COURSE FOR COUNTY SOCIETIES

Third Month—Second Weekly Meeting

ACUTE ARTICULAR RHEUMATISM[1]

PATHOLOGY: Changes in synovial membranes, periarticular structures, cartilages, effusion, tendon sheaths. Changes in endocardium, pericardium, myocardium. Blood changes.

CLINICAL HISTORY: Prodromata, fever, angina, etc. Invasion, fever, chills, synovitis, pain, swelling, perspiration. Duration, defervescence.

COMPLICATIONS: Hyperpyrexia—Time of onset, cerebral symptoms, prostration.

Cardiac Affections—Endocarditis, frequency, time of onset, *termination, diagnosis. Pericarditis, occurrence, forms,* symptoms, physical signs. Myocarditis, association with other lesions, dilatation.

Pulmonary Affections—Pneumonia, pleurisy, accompanying cardiac lesions.

Nervous complications—Delirium, coma, convulsions, chorea, meningitis.

Skin Lesions—Sudamina, erythema, urticaria, purpura. Subcutaneous nodules, distribution, pathology.

TREATMENT

PROPHYLAXIS: Exposure to cold, occupation, local predisposition, tonsilitis.

Internal Medication—Salicylate acid, its compounds. Physiologic action. Therapeutic action. Untoward effects. Antipyrin and acetanilid. Alkaline treatment.

Local Applications—Counter-Irritants. Cold and Heat. External applications.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

ARKANSAS: Regular, Little Rock, November 14. Sec., Dr. F. T. Murphy, Brinkley; Homeopathic, Little Rock, November 14. Sec., Dr. P. C. Williams, Texarkana.

CONNECTICUT: Regular, City Hall, New Haven, November 14. Sec., Dr. Charles A. Tuttle, 196 York Street; Homeopathic, Grace Hospital, New Haven, November 14. Sec., Dr. Edwin C. M. Hall, New Haven; Eclectic, Hotel Garde, New Haven, November 14. Sec., Dr. Thomas S. Hodge, 19 Main Street, Torrington.

LOUISIANA: Homeopathic, New Orleans, November 13. Sec., Dr. J. T. Crebbin, 1207 Maison Blanche Building.

MAINE: City Council Rooms, Portland, November 14-15. Sec., Dr. F. W. Searle, 776 Congress Street.

MASSACHUSETTS: State House, Boston, November 14-16. Sec., Dr. Edwin B. Harvey.

TEXAS: Fort Worth, November 14-16 (change of date from previous notification). Sec., Dr. J. D. Mitchell.

WEST VIRGINIA: *Hotel Waldo, Clarksburg, November 13-15.* Sec., Dr. H. A. Barbee, Point Pleasant.

Missouri June Report

Dr. Frank B. Hiller, secretary of the Missouri State Board of Health, reports the written and oral examination held at St. Louis, June 12-14, 1911. The number of subjects examined in was 14; total number of questions asked, 105; percentage required to pass, 75. The total number of candidates examined was 181, of whom 146 passed and 32 failed. Three candidates did not complete the examination. The following colleges were represented:

PASSED

KENTUCKY STATE MEDICAL ASSOCIATION

Fifty-Sixth Annual Meeting, held at Paducah, Oct. 24-26, 1911

The President, DR. J. E. WELLS, Cynthiana, in the Chair

Officers Elected

A list of the newly elected officers was published November 4, p. 1545.

Axis Traction Forceps

DR. DELIA CALDWELL, Paducah: This instrument is not used as often as it should be. Practitioners should make use of it in all suitable cases.

What the Physician Can Do for the Diseases of Women in His Office and at the Bedside

DR. GEORGE J. HERMAN, *Newport:* More than 90 per cent. of gynecologic patients consult the general practitioner for one of two things, either pain or irregular menstruation. Again, the general practitioner sees for the first time the great majority of women who suffer from malignant disease of the breast and uterus. What can he do for those patients? He must make an early diagnosis, and advise early and radical treatment. I want to emphasize the value of absolute rest in inflammatory conditions of the female pelvis.

DISCUSSION ON PAPERS BY DRS. CALDWELL AND HERMAN

DR. T. A. FRAZER, Marion: Dr. Herman struck the keynote when he says we should put these patients to bed and have them rest. When a woman is suffering from an inflammation of the pelvic viscera, it is just as necessary that she be confined to bed and kept there for a while as is a case of typhoid. There is nothing so important for these cases as absolute rest.

DR. D. O. HANCOCK, Henderson: We do not use forceps enough. If we did, much pain would be obviated and exhaustion guarded against. With a reasonable amount of skill, the damage which may be done by the forceps does not compare with the damage that is done by the head by prolonged pressure and waiting. I can more certainly protect the perineum by having forceps on than I can by taking them off.

DR. J. S. LOCK, Barboursville: Among country practitioners there is a good deal of prejudice against the use of forceps, either on account of lack of skill in using them or to gain the favor of the public. I make it a practice to use forceps if I have a tedious case and can get the parts in proper condition. I think it is just as much our duty to relieve suffering mothers with the use of forceps as it is with anything else that comes in our line of work. The general practitioner is responsible for the infrequent use of forceps, to a great extent. If the practitioner does not know how to use this instrument, he ought to learn how. We ought to begin to educate the people about the use of forceps and about the advantages that come to them from such use.

DR. C. J. SLAYTON, Greenville: I have been engaged in the practice of medicine for forty years. I have used forceps oftentimes, but only when I think it is absolutely necessary. I depend largely on the *vis medicatrix naturæ*. He who practices obstetrics and has patience and waits is the safest man. I did not see a rupture of the perineum for fifteen or twenty years after I began to practice.

DR. J. T. REDDICK, Paducah: I have had a pair of axis-traction forceps for the past six or eight years. No physician who pretends to do very much obstetric practice should be without this instrument because of its value in selected cases. In high forceps cases and in other cases that are difficult, the axis-traction forceps affords speedy relief and its manipulation is easy. I have saved the lives of many infants by the timely use of forceps.

DR. J. B. MURPHY, Chicago: Every obstetrical case is a surgical case. Fortunately, Providence has so ordained that the tissues, lacerated and injured in every surgical case, shall take care of a large quantity of material, unless the dose is very large and of the most virulent type, by the infiltration edema that occurs preceding parturition. It is entirely different when we come to abortion and premature labor. There is where we get out fatal infections. There is where women are killed by interference and manipulation and handling without taking aseptic or antiseptic precautions. We see these cases of infection in their worst forms after they have passed out of the hands of general practitioners, and they come to us in the superlative degree of infection, and we, therefore, as surgeons are very much more afraid of infections than the average practitioner.

Medical Ideals for the Every-Day Doctor

DR. W. W. ANDERSON, Newport: Every great movement for human welfare in promoting health and vigor has been instigated, advocated and carried to success chiefly by the medical profession to its own great loss, and often in the face of bitter opposition from the people who were to be benefited. No other calling or profession has such a record of constant and unselfish devotion to humanity. The every-day practice of medicine is eminently fitted to make the most of any man if he but give himself devotedly to the work for its own sake. The great men of medicine were just hard, earnest and capable workers. They grew great by growing into the greatness of their task. The every-day doctor must do some specializing. Consultations ought to be more frequent. The greatest opportunities in the healing art to-day are waiting at the hand of the general practitioner. When the every-day doctor has learned to excel himself and others in something, he will begin to experience the pleasure of leadership, the distinction of success, the joy inherent in work well done.

Indications for Prostatectomy

DR. FRANK BOYD, Paducah: The indications for the removal of the prostate are that whenever it interferes by enlargement sufficient to prevent the free and complete emptying of the bladder, from whatever cause, it should be removed.

DISCUSSION

DR. JAMES G. CARPENTER, Frankfort: Early diagnosis of enlarged prostate is everything. If the gland is large and situated high up, it is easily reached by the suprapubic route. If it is a comparatively small fibrous prostate, it can be removed by the perineal route.

DR. CARL WHEELER, Lexington: Residual urine does not always mean enlarged prostate. We may overlook contracture at the vesical neck or hypertrophy of the prostatic fibers at the vesical neck, which is to be differentiated from prostatic hypertrophy by the increased length of the urethra. In hypertrophy of the prostate the patient has an increase in the length of the urethra. Preparation of the patient for prostatectomy has not been touched on. In many instances the renal function is deranged, and the administration of an anesthetic may mean almost certain death. If you introduce a drainage catheter and anchor it, you will see the specific gravity of the urine increase from 1006 to 1020. The albumin in the urine will greatly disappear, but not entirely. The appetite of the patient will improve. The patient will take on flesh. The kidney function will almost be reestablished, and the surgical risk is greatly minimized, and prostatectomy is never indicated until all these things are found out.

DR. JOHN R. WATHEN, Louisville: I have contended that it is far better to operate suprapubically where the prostate is soft, large, of the adenomatous type, rising high up in the bladder. It enables one to make a better diagnosis of other lesions which may be present. The perineal method is indicated in 90 per cent. of the cases.

DR. L. W. BREMERMAN, Chicago: The functional activity of the kidneys should be estimated in every case, not only when prostatectomy is indicated, but when any other operative procedure is contemplated on the genito-urinary tract.

Early Diagnosis in Malignant Disease

Dr. William H. Wathen, Louisville: We are able to make a reasonably early diagnosis of cancer in certain parts of the body, while in cancer situated in other parts we make a very late diagnosis—too late in many instances to do any good by surgical operation. I have operated in numerous cases of cancer of the uterus in the last thirty years, and in many others I have not operated at all. In from 80 to 90 per cent. of the cases it was too late to offer any hope of a permanent cure by operative procedure. We can only offer temporary relief and the prolongation of life of from six months to one year. It is a sad commentary on the intelligence of womanhood and on the medical profession that when we recognize most of the cases of mammary cancer they have progressed too far for any hope of permanent relief.

Early Diagnosis in Ano-Rectal Diseases

Dr. J. G. Carpenter, Frankfort: Early diagnosis in anorectal diseases is everything. Too often the physician has accepted what the patient has said with reference to his condition. If a patient will not submit to a proper objective examination, he has no right to be treated. I have seen young children with summer diarrhea in whom there were fissures, hemorrhoids, aphthous ulcerations, proctitis. When the patients were treated by divulsion of the rectum and the use of antiseptics, the summer diarrhea has subsided and these patients have recovered.

Early Diagnosis of Head Injuries

Dr. A. D. Willmoth, Louisville: In the brain, of all structures, do we have to make an early diagnosis, if we expect to get the best results. This may not mean a surgical result. Many times it means doing nothing. If we would make an early diagnosis, we have to do away with the old classification of concussion and compression of the brain. There is one condition in brain injuries that brings about the entire trouble, and that is increased intracranial pressure. If it be an injury, you may merely have an extravasation of blood as in any other part of the body or tissue, and it causes great disturbance. A good history of these cases will guide one in the subsequent treatment.

Ectopic Pregnancy

Dr. Hugh E. Prather, Hickman: Abdominal section is the only reliable method for the relief of this condition. Without surgical treatment about two-thirds of the patients die. When rupture occurs the patient may suddenly collapse and fall to the floor, or present symptoms which simulate salpingitis, appendicitis or uterine abortion. Surgical treatment should be instituted as soon as the diagnosis is tentatively established, except when the patients are *in extremis*.

DISCUSSION

Dr. W. W. Anderson, Newport: Surgery is so safe and swift and sure that we ought to consult the surgeon for diagnosis a great deal oftener than we do.

Dr. J. G. Carpenter, Frankfort: In ectopic pregnancy we should be able to make a diagnosis before rupture. The patient may feel in unusually good health, but suddenly falls over when in the act of doing something and faints, or she is seized with a violent pain in the lower part of the abdomen and says, "I am dying." These, with other symptoms should enable the practitioner to make a diagnosis. With a diagnosis of ectopic pregnancy the patient should be kept in the best possible condition, and when the attachments of the afterbirth are maturing and ready to undergo degeneration, operation should be performed.

Dr. J. T. Reddick, Paducah: When there is a rupture in the early stage of pregnancy, it is small, and the hemorrhage is so slight that one may not be able to make a diagnosis for several hours. I recall one such case in which it was impossible to say whether or not it was a case of ruptured ectopic pregnancy or appendicitis or acute intestinal obstruction.

MISSISSIPPI VALLEY MEDICAL ASSOCIATION

Annual Meeting, held at Nashville, Oct. 17-19, 1911

(*Concluded from page 1558*)

Medical Tendencies

Dr. Robert H. Babcock, Chicago: So indispensable have laboratory methods become to-day that one wonders how clinicians of fifty years ago succeeded as well as they did in the diagnosis of any but the commonest affections. Is there not a tendency, along with devotion to laboratory research and animal experimentation, to make the study of pathology outweigh too greatly the application of remedies to the alleviation of disease? In how many schools of to-day do the students receive the instruction in materia medica and therapeutics they did thirty years ago? There is reason for this therapeutic skepticism, but it is a tendency which should not be permitted to grow too rank lest the art of healing be lost in the science of investigation of disease processes. Medical colleges must enlarge their clinical facilities or it may be well to return to the good old custom of each student having a practical training with an experienced preceptor. No one can contemplate present therapeutic methods and contrast them with those of three or four decades ago without recognizing that a momentous evolution is at work.

A national department of public health in all probability is only a question of time. It certainly is in accord with popular education on matters of health and hygiene and the movement springs from the humanitarian desire for the physical betterment of the masses.

Doctors and the People

Dr. J. C. Wilson, Philadelphia: The organization of the medical profession but lightly touches the people and the discipline reaches them not at all. There are many people who are wholly indifferent to the medical profession; some who are actively hostile to it. Modern medicine is preventive medicine. To attain its objects, which are the protection of health and life, no effort is too arduous, no problem too difficult. Wherever disease prevails, wherever the death-rate is high, it wants to know the cause in order that the remedy may be applied. It busies itself with water, milk, foods of every kind, even the air we breathe. It goes to the school, the mine, the factory, the shop, even to the very homes of the people to correct the faults that menace health and life through ignorance and neglect. It invokes the law that people may be protected from themselves and from each other. It is in the highest sense educational. It invites reasonable criticism of its methods and results. It should have the interested cooperation of those who reap the benefit of its work.

The Indebtedness of Posterity to the Pioneer Surgeon of the Mississippi Valley

Dr. Joseph C. Bryant, New York, in the address in surgery, paid a glowing tribute to Dr. Ephraim McDowell, the first surgeon to perform ovariotomy.

General and Dietetic Treatment of Typhoid

Dr. George Dock, St. Louis: The efficient preventive treatment now available should be used in camps and in institutions or wherever bodies of people are gathered together under conditions that might make typhoid infection possible. The preliminary use of calomel can be carried out without danger of setting up dangerous diarrheas. It is important to keep up the patient's nutrition to the highest possible point in order to favor recovery of the anatomic lesions. The fuller diet recommended by many recent authorities does not involve any greater danger to the intestinal wall than the administration of milk. A comparatively varied diet can be given without exciting the patient in any way, and the morale of the patient is nearly always distinctly improved by realizing that he is not on the painfully limited diet traditionally given to seriously sick people.

DISCUSSION

Dr. Charles L. Minor, Asheville, N. C.: We ought to use all the various means of giving water to our patients, of pushing water on them, having the nurses insist that they get so much water at a time and as regularly as medicine. I have for the last two years in a number of severe cases, infused my patients, and I have been surprised to see the wonderful effect of a twice-daily saline infusion.

Dr. Fenton B. Turck, Chicago: It is a mistake to inject a large quantity of water into the bowel of a typhoid patient, for the reason that it overstretches the colon, increases the cramps and does not produce a true peristalsis.

Dr. John A. Witherspoon, Nashville: In my typhoid experience, sweet milk, if given at any stage of fever, and especially after the beginning of the second week, will invariably increase fermentation to the extent that there will be a great deal more gas in the abdomen, and a great deal more flatulency. Then in the stool large masses of curdled milk will be found passing through. Any diet that increases flatulency and fermentation, and that is capable of passing through the intestinal tract in a coagulated form, is not the best diet. I believe in nutrition, but sweet milk, in my judgment, has no place in the treatment and dietetics of typhoid fever. If one gives the patients buttermilk, or broths, or meat juices, or extracts, one will get much better results, and maintain the vitality of the patient better.

Dr. L. H. Montgomery, Chicago: I am an advocate of soups and beef-extracts, properly prepared, but I use milk and buttermilk. I give custards and poached eggs, recommend sunshine and plenty of clean sheets and bedding, and general hygienic rules.

Dr. Robert B. Preble, Chicago: The keynote of this discussion is individualization: there are patients who can be fed successfully on sweet milk without disturbance; some can be fed nothing but water and not feel any disturbance, and there are others to whom we may give a liquid diet. But each patient must be handled as an individual, and any man who attempts to treat every patient with a fixed diet that applies to all patients will have a lot of trouble.

Hemorrhage in Typhoid Fever

Dr. Walter F. Boggess, Louisville: For the past fifteen years it has been my habit to give every typhoid patient 5 grains salol, 10 grains hexamethylenamin, 20 grains each of subnitrate and subgallate of bismuth, in suspension, every four to eight hours. This is given with a dose of castor oil every three or four days, and normal saline enemata each day, whether or not diarrhea is present. In 223 cases of typhoid fever thus handled not a single one showed any hemorrhage. Three severe hemorrhages occurred in ambulatory patients, and my first visit was during the hemorrhage. I feel sure that this treatment is prophylactic and curative.

As to the treatment of the hemorrhage itself, at first glance, the indications are threefold: first, to put the bowel at rest by lessening peristalsis; second, increase the coagulability of the blood, either local or systemic or both, and, third, to sustain the patient and the after-treatment, which is a matter of some importance. Prophylaxis is a matter of great importance, as obtained by the proper handling and treatment of the patient.

Dr. George Dock, St. Louis: The first thing to do in such cases is to give the patient enough morphin to quiet him. I have hardly seen one who did not need quieting. When to move the bowels is an important point, and I have come to solve this in a rather empirical way. As long as the patient is comfortable, I often wait three or four days, but if he shows the slightest discomfort in the lower bowel, I do not hesitate to give him an enema, either saline solution, or even soap-suds enema containing castor oil. I think this better, even if a little hemorrhage is started.

Hygienic and Dietetic Treatment of Arterial Hypertension

Dr. Arthur R. Elliott, Chicago: We must not lose sight of the fact that high blood-pressure is a symptom, not a disease. In the present state of our knowledge hypertension appears to be due to toxemia, certain secondary organic changes, arterial fibrosis and cardiac hypertrophy, following from over functioning of the cardiovascular apparatus produced by the circulatory toxins. The existence of arterial hypertension is not necessarily an indication for treatment. It is difficult often to decide whether we should attempt to lower blood-pressure at all in any given case. A blood-pressure of 200 mm. or higher may be essential to the maintenance of circulatory efficiency. This is true of most cases of chronic nephritis. Again, the symptoms ordinarily attributed to high blood-pressure may be more dependent on disturbance of heart function than on elevated blood-pressure *per se*. Even in matters of diet and hygiene we may by overstrictness impair the patient's strength and reduce his circulatory efficiency. This symptom is encountered alike among the rich and the poor, the thin and the fat. Owing to variation in type and circumstances, it is difficult to lay down any absolute rules to govern diet and hygiene that will be appropriate for any major group of cases.

Preliminary treatment should be directed toward putting the patient in as good general condition as possible, and especially to eliminate toxic factors. Tobacco should be interdicted in severe cases and cases with bad hearts, and strictly controlled in all. Exercise and activities should be regulated on the physiologic level. Such rest should be enforced and periodical "bed weeks" advised in cases of weak hearts. The diet should be individualized according to age, activity, and the state of the heart. Hypertension waves or crises should be combated by rest, starvation or a low diet, of milk and cereals, or bread and fruit with limitation of fluids. Fluids should be restricted in ratio to the amount of urine secreted. Salt restriction is advisable in all cases, and salt withdrawal in every case showing edema, however slight. As these patients are very nervous and impressionable, they should be habitually encouraged and should not be informed of the fluctuations in their blood-pressure.

DISCUSSION

Dr. Alfred C. Croftan, Chicago: An important point in Dr. Elliott's paper is that not every case of hyperarterial tension necessarily calls for suspicion or regulation. This is simply a broad rule which applies to almost every morbid phenomenon. It may call for regulation, it may call for suspicion, or it may call for encouragement. A symptom of that kind may be one of the means of defense against disease. As to diet, I have been inclined to the mechanical rather than the chemical side. I try to give these patients a diet which does not distend the stomach and colon unduly with salads, liquids or gas. The diastolic action of the heart is always difficult in these cases, and anything that presses upward on the diaphragm is not good. Hydrotherapy is of the greatest importance.

Dr. Robert B. Preble, Chicago: The successful handling of these cases requires, first, that our knowledge must be more complete than it is now, so that we may be able to direct our patients intelligently. Second, our patients must be sufficiently intelligent to carry out the directions which we give them. Third, the very practical difficulty which we frequently encounter is a question of dollars and cents. These conditions are extremely common among the poor, and it is useless to talk to the average poor patient about these things you would like to have him do that would be for his good.

Dr. Albert E. Sterne, Indianapolis: In some instances these cases will react to simple mechanical treatment, but in those in which there are manifest cardiovascular changes and commensurately strong central action, systematic venesection is one of the best remedies. It is true that after a comparatively shorter or longer lapse of time the rise in peripheral tension recurs, but systematically carried out I have found venesection in selected cases a valuable therapeutic agent.

The Treatment of Movable Kidney

Dr. William Billington, Birmingham, England: I have operated for mobility of one or both kidneys on 345 patients and have performed more than 500 fixation operations. In many instances, I have tried the effect of mechanical support prior to nephropexy. Amelioration of symptoms, when the kidney is efficiently supported, is a strong argument in favor of nephropexy, should the belt fail to give complete relief or be too irksome for permanent employment. Congenital cases of general visceroptosis are unsuitable for operation. Open operation alone insures permanent and complete cure of renal mobility. Nephropexy can now be carried out with safety, precision, and permanent success, and there are no surgical reasons why it should not be done in suitable cases. The operation is analogous in all respects to the radical cure of hernia, the same general rules applying to each procedure. Given a patient whose symptoms demand treatment for mobile kidney, the choice between belts and trusses or operation will be determined by the type of displacement, the nature of the symptoms, and the age, occupation, and general condition of the patient.

With regard to my results, I have to record three deaths among 345 patients, a mortality of less than 1 per cent. In 166 of the 345 patients, one kidney only was operated on, while in 179 both kidneys were fixed at the same sitting. The total number of nephropexies is 524. Of the single operations, 130 were on the right kidney and thirty-six on the left. Thirty-three of the patients were males and 312 females. Of the latter, 148 were married and 164 single. My youngest patient was a boy of 14, and my oldest a woman of 70 who suffered from agonizing pains in the right side on the least exertion, the cause of the pain being torsion of the right renal pedicle. Most of my patients were between 35 and 45, but my experience has been that no period of life is altogether immune from the more serious troubles associated with nephroptosis.

Nephroptosis: Its Effect on the Nervous System, with Special Reference to Insanity

Dr. C. W. Suckling, Birmingham, England: My views are based on twenty years' work and on the observation of over 400 nephropexies performed on 303 patients. I was astounded at the frequency with which I found dropped kidney. I could not help associating the dropped condition of the kidneys with the nervous trouble of which the people complained. I tried various kidney belts, but found they did not keep the kidneys up. I have now had at least 300 cases of operation. I have seen the kidneys, and have observed the changes that take place with age. I have seen the normal kidney, the suprarenal capsules occasionally, but very rarely descending with the kidney, the colon dragged out with the movable kidney, also the duodenum. I have also seen ptosis of the spleen with nephroptosis. I have visited these patients after nephropexy, and have observed the wonderful change in their appearance after a few days. Forty-three of my insane patients treated by nephropexy are cured; five cases are failures, of which two are so owing to bad nephropexy.

Treatment of General Peritonitis, Based on Personal Experience

Dr. Daniel N. Eisendrath, Chicago: I have had thirty-two cases in seven years with three deaths; twenty-two in the past three years with two deaths. The causes of death were acute dilatation of the stomach, general sepsis and uremia in one case, phlegmon of abdominal wall in another, and initial general sepsis in the third. One additional patient, who died of pneumonia one month after operation, had been well and up for nearly two weeks. There were ten patients operated on the first day, with no deaths; twelve on the second day with one death; seven on the third day, with one death. In the majority of cases there were no previous attacks due to the organ involved.

The most valuable symptoms are increase in pulse-rate, spreading rigidity and tenderness, persistent nausea and vomiting; uncertain signs or the presence of fluid and absence of liver dulness. The distention comes on too late, as a rule, to be of much value. Fever also is not reliable. The white blood-count was increased in all cases, except the most severe one. Urinary findings are of importance in regard to prognosis.

The peritoneal changes were typical in all cases. In twenty appendicitis cases there was a visible perforation. In eight there was none. Peritonitis was general so far as I could see. Rapid operation is a necessity. The right rectus incision was made in all cases. This is sutured, except a small drain is inserted at the lower angle down to the peritoneum. As soon as the appendix has been removed, or the perforation has been closed, an incision is made just above the pubes and a drain is inserted into the cul-de-sac. A split rubber-tube, well protected, is the best drain. The maximum amount of drainage is obtained in the first twenty-four hours. The high elevation of the patient after operation is essential. No irrigation is resorted to during the operation. Salt solution, 6 ounces, is given every four hours after operation, and this has been found to be plenty and is better tolerated by the majority of cases. The surgeon should watch for complications, especially acute dilatation of the stomach. Abscesses between the coils of intestine will usually take care of themselves or can be opened later if the fever should persist.

Approval of Dr. Wiley's Work and of a National Department of Health

The association put itself on record as expressing its appreciation of the valuable work which has been done and is being done by Dr. Harvey W. Wiley in the enforcement of the Food and Drugs Act. The association also, following the recommendation of the president, Dr. Babcock, in his address, appointed a committee which drafted resolutions urging the importance of establishing a national department of health

COLLEGE OF PHYSICIANS OF PHILADELPHIA

Meeting held Oct. 4, 1911

The President, Dr. George E. deSchweinitz, in the Chair

Hydrophobia

Dr. Leonard D. Frescoln: History shows that knowledge of the disease dates back to the time of Celsus. Early ideas of the disease were very crude. Virchow showed the fallacy of its spontaneous origin, and Samuel Johnson called it "a substance, nobody knows what." It is found most commonly in the spring. One writer said it could occur as long as twenty-eight years after the bite. The incubation period is between ten days and one year—generally about six weeks. In Egypt the disease is unknown; in Missouri and Ohio it is common; also in Hamburg and in Saxony. The gross pathology is for the most part similar to that of uremia, or septicemia, or delirium tremens. One case had a ruptured pleura from the convulsions; glycosuria may be found in dogs with the disease. In 1903, Negri noticed degeneration of cortical nerve cells in rabies cases. Among the most striking symptoms now found to be indicative of the disease, are irritability, sensitiveness of the ears to sound, spasm of the pharyngeal muscles, especially when trying to swallow, painful consciousness and later paralysis. It is yet a long road to the complete satisfaction of particularly the laity in the diagnosis and treatment of rabies. Dr. Hunter stated that not one case had been helped in 2,000 years. Ward, in 1809, advised the external use of opium; entrails of insects were used in India to cure the malady, and many superstitious modes of treatment were in vogue. Now we cauterize the wound at once with fuming nitric acid, administer chloral and give the Pasteur preventive treatment as early as possible.

In 1895, eleven persons were given this treatment, and in 1907, 165 in Massachusetts alone. In 1886, there were 2,671 patients treated in Paris, and twenty-five of these died, probably because treatment was delayed; in 1910, there were 401 persons treated and not one died. In 1899, in the District of Columbia, twenty-one persons were bitten, Pasteur treatment instituted, and not one died. There is no case of the fully developed disease in which the patient has ever recovered.

Rabies has been eradicated from Denmark, Norway, Sweden, England (1897) and Switzerland. In Australia there is a six months' quarantine for newly arrived dogs. Pseudolyssa or hysteria resembling rabies, may closely simulate the disease. During the last few years about sixteen persons under our observation were treated, either for the disease or on account of suspicious bite from animals shown to be rabid and having Negri bodies; in one or two cases, Negri bodies were found at autopsy. All persons receiving our treatment escaped the disease. Treatment was given before convulsions developed. The cases seen in the disease terminated fatally. There should be a proper selection of cases and careful institution at once of the best known treatment. About twenty-five treatments of the Pasteur method or required, one a day, as shipped, e. g., from the New York Board of Health; this costs $25. Each bottle should be kept on ice till injected that day.

DISCUSSION

Dr. D. J. McCarthy: An important point in diagnosis is the period of incubation, which is usually about six weeks. In almost all the spurious cases of rabies I have seen the incubation period was much too early or very much too late. In examining a case of suspected rabies I feel that it is important to work out carefully the question of exposure, history of dog-bite, and to estimate the period of incubation. One condition mistaken for rabies and in which the similarity of symptomatology is marked is enlarged thymus.

Dr. Hobart A. Hare: To anyone wishing to investigate the subject of rabies, an instance of interest is the occurrence of an epidemic of the disease in the royal herd of deer near London in 1888. A number were at the Brown Institution, where I saw them with Sir Victor Horsley and Dr. Beavor. The viciousness of the animals, which ordinarily are so gentle, was very marked.

Dr. A. P. C. Ashhurst: It is worthy of notice, I think, that in these cases only those patients recovered whose wounds had been treated properly; and that patients whose wounds had not received proper treatment had died in spite of the use of the Pasteur treatment. Dr. Rambaud, head of the Pasteur Institute in New York, asserted that cauterization was useless unless the actual cautery was employed, and he considered bichlorid of mercury (1 to 1,000) the best antiseptic. It has been suggested that lemon juice might be employed in an emergency, as this has been found of value in experimental work. If it was certain that the bite had been inflicted by an animal which was really rabid, a cupping glass should be applied to the wound, or this should be sucked, so as to extract the virus; and its absorption might be delayed by the use of an elastic tourniquet. I should like to ask Dr. Frescoln what method of cauterization he employed in the cases reported.

Dr. L. D. Frescoln: Fuming nitric acid or crude phenol was used immediately to cauterize.

Compensation by Displacement of the Thoracic Viscera in Pulmonary Tuberculosis

A long abstract of this paper by Dr. Charles L. Leonard appeared in The Journal, Oct. 21, 1911, p. 1393.

DISCUSSION

Dr. Henry R. M. Landis: I should like to ask Dr. Leonard how many cases came to the autopsy table, because even where the clinical results and the roentgenograms have been compared, experience has shown that a different condition is sometimes present. I should also like to ask whether the pneumothoraces were recognized by clinical examination or by the plates only. I should think it would be difficult to detect any displacement of the aorta by clinical means, and I should like to inquire how often the clinical examination of displacement of the aorta coincided with that found in the Roentgen examination.

Dr. James M. Anders: I was somewhat surprised to hear the statement made that the heart is displaced toward the right four times as often as toward the left in pulmonary tuberculosis. In making physical examinations in cases of tuberculosis, one is led to believe that the heart is displaced toward the left, because the left lung, when retracted, uncovers an increased area of the anterior surface of the heart, giving the impression that the latter is displaced toward the left. This group of cases is readily eliminated by the Roentgen ray. Dr. Leonard has pointed out that in the vast majority of cases in which there is displacement of the heart toward the right, the aorta is also displaced; this had not been discovered by the clinician prior to the introduction of the Roentgen-ray method of studying cardiovascular diseases. One reason that the heart is displaced more frequently toward the right than toward the left is doubtless the fact that the hydropneumothoraces are more common on the left than on the right.

Dr. Charles L. Leonard: The superficial hydropneumothoraces were discovered by the physical signs only, after the Roentgen examination showed them to be present. The fact that we have the anteroposterior position produced by the heart has led me to believe that in many cases the supposed frequent occurrence of a decrease in the size of the heart in tuberculous cases is due rather to a change in the position of the heart than to a change in the size. As Dr. Anders has said, the drawing away of a portion of the lung from the right has led to the idea of its hypertrophy. I have studied these cases from the roentgenologic standpoint, rather than from that of the internist. We have compared all the cases with the clinical findings, and the result of the roentgenographic findings is what I have presented in my paper.

Book Notices

Lehrbuch der Therapie innerer Krankheiten für Aerzte und Studierende. Band I. Allgemeine Therapie innerer Krankheiten. Herausgegeben von Dr. Paul Krause, Professor und Direktor der Medizinischen Universitäts-Poliklinik in Bonn, und Dr. Carl Garre, Professor und Direktor der chirurgischen Universitäts-Klinik in Bonn. By various authors. Paper. Price, 11.50 marks. Pp. 758, with 345 illustrations. Vienna: Gustav Fischer, 1911.

This is an excellent treatise by some of the more noted clinicians of Germany and promises to be of unusual worth from its thoroughness and practical character. Evidence of the first quality is furnished by the passage which gives the application to the administration of remedies of the more recent facts regarding the absorbability of different substances from the stomach—the first attempt we have seen to make this application. Professor Magnus remarks in this connection that on account of the difficult absorbability of most medicines from the stomach, we are to consider the time which they stay in that organ as lost time and that their action begins only at the time when they are expelled from the stomach into the intestine.

A Text-Book of the Practice of Medicine. By James M. Anders, M.D., Ph.D., LL.D., Professor of Medicine and Clinical Medicine at the Medico-Chirurgical College, Philadelphia. Tenth Edition. Cloth. Price, $5.50 net. Pp. 1328, with 81 illustrations. Philadelphia: W. B. Saunders Co., 1911.

The present edition of this manual has undergone a more thorough revision than its predecessors, with the addition of much new matter. The list of topics revised or considered the first time includes over forty titles. The attempt to confine the work largely to the more practical aspects of medicine, etiology, diagnosis and treatment makes it possible to present a vast amount of useful information within the compass of a single volume. Still so much condensation becomes necessary that some of the more important topics receive a mere notice. Thus the glycyl-tryptophan test for gastric cancer is dismissed in a line which leaves the student as ignorant as before of its nature or significance. It may be questioned whether such references as this are of any practical value, although, of course, their omission would lay the work open to the charge of incompleteness. On the whole the book is well adapted to meet the needs of the general practitioner who may find here authentic information, well up to date, without discussion of disputed points, for which he may consult other works or periodical literature.

Clinical Lectures on the Acute Abdomen. By William Henry Battle, F.R.C.S., Surgeon to St. Thomas's Hospital. Cloth. Price, $1.50 net. Pp. 107, with 10 illustrations. New York: William Wood & Co., 1911.

These lectures are collected to make seven chapters: I, The Influence of the Appendix Vermiformis and Its Diseases. II, The Treatment of Acute Appendicitis with Peritonitis. III, Pathologic Perforations of the Digestive Tract. IV, Acute Intestinal Obstruction. V, Diseases of the Female Generative Organs. VI, Some of the More Rare Causes of the Acute Abdomen. VII, Some Neuroses Which May Cause Symptoms of Urgency. Many of the conditions discussed are illustrated by case reports, thus adding to the value of the text. Where operation is indicated, the procedure particulary adapted to the case is described in a manner enabling even the tyro to do the operation. The author repeatedly emphasizes his preference for silk sutures and ligatures. He believes that catgut should not be used in acute abdominal cases because it is apt to soften and yield too quickly. He always uses silk.

Medicolegal

Members of Board of Health Not Liable for Damages from Fumigation—Construction of Health Laws—Power to Quarantine Against Local and Interstate Points

(Allison vs. Cash and others (Ky.), 137 S. W. R. 245)

The Court of Appeals of Kentucky affirms a judgment holding that the defendant sheriff and members of the Lyon County board of health were not liable for damages sustained by the plaintiff in having her store fumigated, etc. The court says that the laws from which the boards of health derive their powers should be liberally construed that they may not be needlessly restricted in their efforts to preserve the public health; otherwise the health officers would be unable to know their duties and so embarrassed in their performance as to hesitate to act, until irreparable injury has resulted to the public.

In the court's opinion, the power, as for example of the Lyon County board of health to establish quarantine for the benefit of Eddyville against Kuttawa, is impliedly, if not expressly, conferred by Section 2055 of the Kentucky Statutes. But, while the powers enumerated by that section seem sufficient to authorize a county board of health to establish and maintain quarantine in behalf of one city or county against another city or county within the state, such power cannot be exercised by a county board or the state board, as against another state or county thereof, without express legislative authority specifying the conditions and limitations on which such quarantine shall be maintained. In the absence of such legislative authority, the enforcement of quarantine regulations by one state against another would violate the comity that should exist between them and perhaps constitute an interference with interstate commerce.

However, aside from the question of whether the Lyon County board of health exceeded its powers in establishing quarantine against the town of Kuttawa, it clearly had under the general powers conferred by Section 2055 authority to compel the closing of the plaintiff's store for disinfection and likewise to quarantine her, either by requiring her to return to her home in Kuttawa, or be quarantined at some isolated place in Eddyville for the time specified in the notice, as the bringing of her son to the latter place from the infected town of Kuttawa gave her an opportunity to become infected with small-pox, and the leaving of his cast-off clothing in her store afforded danger of infection to her customers. In having her son taken to Eddyville, placing his clothes in the store, and refusing her consent to the temporary closing of the store for disinfection, the plaintiff violated the rules and regulations established by the county board of health and put in force in Eddyville for preventing small-pox from breaking out in that city. In thus dealing with the plaintiff and her property, the defendants not only acted in pursuance of the powers conferred by this section of the statutes, but also in conformity to the rules and regulations of the state board of health.

A board of health is an instrumentality of government created for convenience and invested with such powers as will enable it to protect the general health of the people of the state, county or community over which it is given jurisdiction.

The acts of the defendants complained of in this case did not, according to the proof, constitute in the meaning of the constitution or laws of the state the taking of private property for public use; nor did they result in such an injury to or destruction of the plaintiff's property as authorized a recovery. Fairly viewing the evidence, the acts of the defendants in closing the plaintiff's store, disinfecting her goods, and in requiring her to elect whether she would temporarily return to her home in Kuttawa or be for a stated time quarantined in an isolated place in Eddyville were reasonable and lawful measures adopted by them as members of the county board of health for the suppression of an extraordinary outbreak of small-pox, and were rendered unavoidable by the plaintiff's conduct in violating the regulations established by the defendants, acting as members of the local board of health, in taking her child from the infected town of Kuttawa to Eddyville, and placing his probably infected clothes in her store.

Nor was there any evidence to show that the defendant Cash's connection with the transactions in question put his conduct in a light different from that of the other defendants. As sheriff he merely obeyed the orders of the local board of health in closing the plaintiff's store. This he was bound to do.

It seems to be well settled that a health officer who by statute is authorized to take action for the prevention of the spread of disease is not liable for injuries resulting from such reasonable and customary measures as he may in good faith adopt or direct for that purpose with regard to persons or matters subject to his jurisdiction.

7 Modification of Wohlgemuth's Method for Quantitative Study of Activity of Pancreatic Function. P. B. Hawk, Urbana, Ill.

1. Tonus for Movements of Alimentary Canal.—Cannon's observations have convinced him that double provision is made for the establishment of a state of tonic contraction in the alimentary neuromusculature. Almost the entire length of the digestive canal is supplied with extrinsic nerves which, when stimulated, cause an increase of tone and when destroyed leave the canal at first in a toneless state. And if the canal is entirely separated from the central nervous system it has a remarkable power of developing an independent tonic state. When thus isolated, the canal regains its characteristic movements only as it recovers tone. Tonus is therefore fundamental. It supplies the resiliency that causes the state of tension when the canal is filled, or establishes the state of tension when the canal is only partly filled. The state of tension is the occasion for the contraction of viscera which are walled with smooth muscle holding a nerve net. Refractoriness to stimulation during contraction, and gradually increasing irritability during relaxation, result in a rhythmic response to the condition of tension. The most characteristic feature of the movements of the alimentary canal, their rhythmicity, can thus be accounted for.

The view that tonicity of the neuromusculature of the alimentary canal is a fundamental necessity for the appearance of rhythmic movements harmonizes many diverse observations. It accounts for the failure of efficient motility in atonic states of the stomach and intestines. It gives a reasonable explanation for the existence and importance of extrinsic motor nerves. It is in agreement with the observation that tonic contraction and rhythmic peristalsis disappear together in cases of general bodily weakness, when the depleted central nervous system may be supposed to fail to deliver the necessary tonic impulses; it is also in agreement with the observation that worry, anxiety and distress stop gastro-intestinal movements, for such states, accompanied by splanchnic impulses, abolish tonus. It fits admirably with the fact that the stomach of hungry animals is strongly contracted, for then the tonic state makes the organ ready for instant action on swallowed food. Indeed Cannon is inclined to believe that the sensation of hunger results from tonic contraction of the empty stomach. These are only some of the conditions in which the importance of tonus for movements of the alimentary canal is manifested; doubtless other conditions will suggest themselves.

2. **Brill's Symptom-Complex.**—Brill's symptom-complex is regarded by Friedman as being identical with mild and moderately severe cases of typhus fever.

4. **Incoagulable Nitrogen of Puncture Fluids.**—In view of the demonstration of a proteolytic enzyme or enzymes in carcinoma and sarcoma, it occurred to Morris that a ferment, if secreted into a serous fluid, might disclose its presence by an increase in the quantity of incoagulable nitrogen. In all, twenty-five fluids have been available for examination up to the present time. It would appear that a puncture fluid with incoagulable nitrogen below 0.07 gm. per cent. is probably not of malignant origin. There appear to be at least two possibilities, either that a non-carcinomatous fluid occasionally shows a very large amount of incoagulable nitrogen, or that the case was in reality one of malignant disease. Morris says that no explanation of the high incoagulable nitrogen in certain carcinomatous fluids can be given at the present time. It is highly probable, however, that it is the result of the action of a proteolytic enzyme. It is possible, too, that an anti-enzyme may account for the low values met with in some of the cancerous fluids. Both of these points are under investigation. An attempt is also being made to determine whether the application of this method to the blood may be of service in the recognition of malignancy.

5. **Influence of Temperature on Output of Heart.**—The results of Wolf's experiments lead him to assume that the work of the heart becomes greater during fevers, provided that blood-pressure remains constant. As fevers affect not only the peripheral blood-vessels but also those of the heart, the resulting impairment of the nutrition of this organ must become the more severe, the greater the increase in the work of the heart. This fact is of importance in the treatment of infectious diseases, inasmuch as the work of the heart is a product of the heart in a unit of time, in conjunction with the blood-pressure. The work of the heart increases, therefore, with the pulse-rate, the cardiac discharge and the blood-pressure.

6. **Experimental Cardiorenal Disease.**—The interesting and valuable work done by the authors is reported at great length, and as justice cannot be done this study in an abstract, the reader is referred to the original article.

16. **Macroglossia.**—Immediately after birth, it was observed that Comroe's patient, a girl, at the time of operation 3 years old, had a very large tongue, which appeared to be normal in every other respect. When the teeth began to erupt, the tongue became very much thicker and many small papillæ appeared on the anterior portion. After the first year, both the tongue and the papillæ became rapidly and progressively larger and appeared to take on a bluish color. About one year ago, the entire tongue became quite sore and there developed rather an alarming hemorrhage, which was controlled with some difficulty. Since then there have been several smaller hemorrhages. There has never been much difficulty in mastication and the speech has been fairly distinct. Physical examination showed a robust, well-nourished child of splendid intellect. The swollen and cyanotic lips were bulged forward by a very much thickened, excoriated, violaceous, papillary mass, which represented the anterior portion of the tongue. When the tongue was protruded, it was found that the anterior half of the organ was considerably hypertrophied and was profusely studded with papillæ varying in size from a small pin-head, posteriorly, to a small pea, anteriorly, and separated by many irregular fissures. Many of the papillæ were pustular and the tongue presented a very angry appearance. The posterior half, however, appeared to be not only healthy but of considerably smaller size, such as might be expected in a child of such age. The anterior margin of the tongue, which protruded between the lips, was about 2.5 cm. in thickness and 5 cm. in width. With the teeth in contact, there was a space of about 2.5 cm. between the incisors. The microscopic diagnosis was lymphangioma. Four months after the operation, the tongue, except for some slight thickening, appeared to be quite normal in every respect.

17. **Malformation of Heart.**—At autopsy on Edward's patient the following conditions were found in the heart: Heart and pericardium enlarged. The heart extended from a point to the right of the sternum to the left nipple. The pericardium showed no changes. The heart presented a remarkable appearance. The larger part of the organ seemed to consist of the right auricle. The right heart composed at least two-thirds of the whole organ. The venæ cavæ was large and distended. The right ventricle was not to be made out on inspection. On dissection the following changes were found: The right ventricle was enormously dilated; the walls thin and the musculi pectinati prominent. The foramen ovale seemed entirely closed, but a probe could be passed through the very much thickened septum at one point. The tricuspid orifice and right ventricle were represented by a mere pit in the mesial wall of the auricle below the foramen ovale. This pit was 8 by 5 mm. Leading from the rudiment of a ventricle, along the anterior portion of the aortic ring could be traced a fibrous cord about 4 mm. in diameter, which was evidently the obliterated pulmonary artery, for it was attached to the ductus arteriosus where that vessel joins the branches of the pulmonary. The left auricle was about normal, but the left ventricle was large. The wall averaged 6 mm. in thickness. The mitral and aortic valves showed no changes. The aorta was very large but smooth and elastic. The ductus arteriosus easily admitted a 2 mm. probe and it was continuous with the first branches of the pulmonary artery, so that the blood reached the lungs through it.

28. **Use of Silver Wire in Opening Kidney.**—From the research made by Cullen and Derge it would appear that in nephrotomy with the silver wire the following represent the main advantages of the wire incision over that of the knife, as obtained in experiments. 1. The amount of bleeding at operation averaged only one-half that observed in the knife incision. 2. The bleeding was readily controlled. 3. There was no postoperative hemorrhage. 4. The resultant infarct was much smaller.

31. **Operative vs. Conservative Treatment of Bone Tuberculosis.**—Huntington is convinced more than ever that the medullary structure, at or near a joint, can, with perfect impunity, be removed in its entirety; this to be followed by complete repair of the resultant bone defect. With added experience and with deepened conviction, he feels warranted in applying this statement to tuberculous disease in other localities than the head of the femur, toward which his efforts were originally directed.

33. **Blood-Supply of Duodenum.**—The supraduodenal artery described by Wilkie supplies what he calls the critical area of the duodenum, the upper two-thirds of the anterior wall of the first part of the duodenum, and the upper third of the posterior wall. Its origin is variable and while in the majority of the cases examined it arose from the upper part of the trunk of the gastroduodenal artery, in other cases it was found springing from the common hepatic trunk, from the right or from the left hepatic branches, or from the cystic artery. In these cases, when injected, it formed a very striking picture and impressed one with the precarious nature of the blood-supply of this part of the intestine. In the majority of the cases injected, the supraduodenal artery had no communication of any size with any other gastric or duodenal artery and the application of considerable force failed to drive the injection beyond this limited area of the duodenum. In these cases the supraduodenal artery appeared to be an end artery. In some cases, however, twigs communicating with the pyloric artery or with the duodenal branch of the right gastro-epiploic artery were plainly visible; the anastomosis was, however, never a very free one. When the supraduodenal artery arises from the gastroduodenal artery it usually takes the form of a short trunk, which, arising on a level with the upper border of the duodenum, soon ends by dividing into a spray of branches giving a characteristic fountain-like appearance, the branches for the most part arching over to the front of the duodenum. In three cases the supraduodenal vessel was of large size and ran outwards along the upper border of the duodenum for several inches, sending numerous branches to both its anterior and posterior walls.

In four of the forty injected cases, there was definite evidence of old duodenal ulceration, undiagnosed before death. In one case this was so definite as to have produced a marked stenosis of the first inch of the duodenum. In three of these cases the scars of the ulcers were situated on the anterior wall of the duodenum in the area supplied by the supraduodenal artery and the branches of this vessel could be traced into the scar tissue and appeared to have little or no anastomotic connection with other duodenal vessels. The origin of the supraduodenal artery in these three cases is of interest. In one case it arose from the left hepatic branch, in another from the common hepatic trunk and in the third case it was represented by two vessels, both arising from the right hepatic branch and running vertically downwards. In the fourth case the scar was situated on the upper border of the duodenum ½ inch from the pylorus. In this case injection of the celiac axis artery, without ligature of its branches, failed to inject the first ¾ of an inch of the upper border of the duodenum, even after considerable force had been applied and left an area of pallor in the apparently healthy duodenal wall around the scar.

On dissecting this specimen, a small supraduodenal artery was found arising from the gastroduodenal artery. It sent only one small branch to this pale area which also received a small twig from the pyloric artery. Whatever be its point of origin, the artery soon divides into several branches. One of these, a small one, usually runs upwards in the gastrohepatic omentum; the larger branches descend to the anterior wall of the duodenum, one or more small branches going to the upper part of the posterior wall. In several cases a ligature was applied to this vessel and the celiac axis artery was then injected. In these cases an uninjected area was left and this corresponded almost exactly to the limits of the critical or ulcer-bearing area. In the majority of cases a second artery was found, springing from the gastroduodenal about ½ inch above its bifurcation and supplying the posterior wall of the first part of the duodenum and sometimes reaching to its second part. This vessel, though not constant, was generally present and Wilkie calls it the retroduodenal artery. The lower third of the anterior aspect of the first inch of the duodenum is supplied by a branch which, arising from the right gastro-epiploic artery or from the superior pancreaticoduodenal artery, turns upwards about ¼ of an inch to the right of the pyloric vein of Mayo.

41. **Clamp for Open Treatment of Fractures.**—The clamp devised by Brown is made from a single piece of metal of good tensile strength and flexibility. His preference is for Russia iron, though silver, vanadium steel and aluminum are serviceable. The clamp consists of two long parallel bands tapering at the lower ends and joined at the upper ends by a cross bar. There are two or three other cross bars equidistant from each other, the lowest somewhat above a point one-half way down on the parallel bands. The cross bars are elevated 1/32 to 3/32 of an inch above the parallel bands on one surface. Each end of the upper cross bar is perforated in such manner as to allow the passage of the corresponding long bands when bent circular. The clamp is made in various sizes adaptable to any of the long bones.

55, **Experimental Poliomyelitis.**—A number of additional observations are cited by the authors which they believe prove their theory that: (1) Poliomyelitis is propagated by dust. (2) That the nasopharynx probably is the point of entry. (3) Acute poliomyelitis is both infectious and contagious. It becomes perfectly evident that prophylactic measures should be most rigidly carried out in order to check the spread of this disease.

62, **Treatment of Fracture of Femur.**—The purposes of Drury's splint in fractures of the shaft of the femur are: 1. To obtain the maximum amount of extension with the least amount of weight attached to the Buck's extension apparatus. 2. To tell at a glance the amount of extension maintained by the Buck's extension. The splint is made of ¼-inch soft pine wood, and consists of two sections—the upper part, of a thin, box-like arrangement a little more than ¾ of an inch wide; the lower part of a long ¼-inch board, which slides into the upper part, with a foot piece extending at right angles.

Before applying the splints the legs are measured and the amount of shortening of the injured leg is noted. The Buck's extension apparatus is applied, first using moleskin plaster. Next, coaptation splints are applied around the thigh at the seat of fracture. The splint is now applied, the upper box-like part extending from the axilla downward to the seat of fracture, and firmly bandaged to the body and upper part of the thigh. The lower part of the splint consisting of a long ¼-inch board which projects into the upper part for at least 2 feet, is now firmly bandaged downward from the seat of fracture to the foot, each part being bandaged separately. Extension is now made on the Buck's apparatus, and the lower part of the splint slides downward from the upper part, carrying with it that part of the thigh and leg below the seat of fracture. To maintain this amount of extension, sufficient weight is attached to the rope of the Buck's apparatus extending over a pulley at the foot of the bed. After the muscular spasm wears off, the amount of weight may be decreased without interfering with the amount of extension.

72. **Vaccine Therapy.**—McDonald cites the histories of two cases of chronic infection which were quickly cured with the aid of vaccine therapy. In both cases other treatment had failed. They were both due to the *Staphylococcus albus* and were treated with stock vaccines prepared by the author.

74. **Treatment of Empyema in Young Children.**—Kenyon reports good results following his method of treating empyema in young infants. He opens the pleural cavity along the aspirating needle, making an opening so small that it will just permit the introduction of a rubber drainage tube, so inserted as to let as *little* pus as *possible escape. This tube is a long* one and is connected with a bottle of warm saline fluid so arranged that the fluid is aspirated into the chest, and dilutes the pus. The operation is very simple and quick, and is not accompanied by shock. The apparatus causes no discomfort to the child, and the escape of the pus is slow and does not cause a pneumothorax. There is little leakage around the tube and mixed infection is avoided. Convalescence is shorter than usual, and drainage is efficient.

76. **Differentiation of Free Gas in Peritoneal Cavity.**—Berg has found that *free gas in the peritoneal cavity, as contra*distinguished from tympanitic distention of the abdominal hollow viscera, is shown by the substitution, for the area of liver dulness and flatness, of a tympanitic resonance, rapidly progressing synchronously from above downward, and from below upward, the last to disappear being the mid-area of liver flatness.

81. **Point of Election in Tuberculosis of Lungs.**—According to McConkey, if the fact that tuberculosis of the lungs is secondary to pleural involvement is once appreciated, it will not be difficult to understand why such a very large percentage of pneumonia and pleurisy cases eventually terminate in phthisis. The bacilli contaminating the serum or lymph *which lubricates the pleural surface are usually phagocyted* or prevented from getting a lodgment on the pleura when the phagocytes have a chance to attack them in this thin film of lymph. The apex is peculiar in this: It has only its own scant lymph transudate which is immediately carried below by gravity. This effect of gravity will be more pronounced in those with a "peaked" apex.

85. **Albumin Reaction of Sputum in Pulmonary Tuberculosis.**—The authors submit a report on the results of the chemical examination of the sputum in cases of pulmonary tuberculosis in the wards of the Montefiore Home. Many of the patients have been in this institution for several years, one even as long as twenty-four years, so that the diagnosis, if made, is quite reliable. On the whole, their results do not confirm Roger's statements to the effect that in every case of tuberculosis the sputum gives a positive albumin reaction. They found some cases of undoubted tuberculosis in which careful analysis of the sputum gave negative results. In forty-two specimens of sputum showing the presence of tubercle bacilli, the albumin test was also positive. It has been their experience that the number of bacilli present in the field has no relation to the amount of albumin found by the chemical test. Some specimens of sputum showing an enormous number of bacilli had only a faint trace of albumin, which was sometimes so slight as to render it altogether doubtful whether the reaction was positive. It appears that the activity of the process has considerable influence on the intensity of the chemical reaction. In active, progressive cases the amount of albumin is greater than in quiescent or healing cases. In fibroid cases the amount is often infinitesimal, or entirely absent. Three cases of tuberculosis, with bacilli in the sputum, which gave negative results at the first examination for albumin, reacted positive at a subsequent one. The lesion in the lungs in all these three cases was rather quiescent, the fibroid changes being quite marked. Seven cases of unquestionable tuberculosis, but in which tubercle bacilli were not found when the sputum was examined, gave a positive albumin reaction, two only faintly. There were also three cases of tuberculosis, with tubercle bacilli in the sputum, and the very specimen giving positive results bacteriologically reacted negatively as regards the albumin reaction. One of these was a case of abdominal malignant growth with general metastases (confirmed by autopsy) and with a complicating pulmonary tuberculosis with bacilli in the sputum. Of the cases of pulmonary emphysema examined, two gave a positive albumin reaction and three were negative. Of five cases of bronchial asthma the sputum was negative in all, while one case of asthma complicated by emphysema and cardiac dilatation reacted positively. The sputum was also positive in two cases of Pott's disease.

87. **Methylene Blue Test of Urine of Cancer Patients.**—Verbrycke is emphatically of the opinion that this test cannot even be credited with giving contributory evidence when positive; nor is a negative reaction of any worth.

91. **Brown-Sequard's Epilepsy in Guinea-Pigs.**—A very extended series of experimental observations was made by Alford on this question and he reports his findings at great length. When watched in their cages the scratching reactions of so-called "epileptic" guinea pigs are seen to be intense, prolonged and poorly coordinated, and to occur more frequently than in normal animals. Preventing this scratching by removing its most potent exciting factor, viz., the body lice, prevents the appearance of "epilepsy" in newly-operated animals and causes it to disappear in animals already "epileptic." The value of section of the sciatic nerve seems to be wholly in the incoordination of movement in the posterior limb that results and causes the scratching reactions to be ineffective. Ineffectiveness of scratching produced by other measures, as, for instance, by removal of the claws of the hind feet, has the same effect. The "epileptogenous" area may be increased in extent in the posterior direction by interfering with the movements of the head. The explanation of the fact that "epileptic" guinea-pigs scratch on stimulation while normal animals do not may be either that the frequent repetition of the scratching movements has made them the reaction of choice in place of struggling attempts, or that disturbances in the skin have made it impossible for the animal to distinguish between stimuli of various sorts. The "complete attack" or convulsion is regarded as a reflex phenomenon in which it is possible to recognize the elements of the scratch reflex somewhat distorted by the disturbance of reciprocal innervation. This conception receives some support from the facts (a) that spinal irritants such as strychnin and caffein increase the ease with which convulsions may be elicited and the severity of the convulsions themselves, while the reflex depressant, alcohol, markedly decreases both these factors; and (b) that operations which increase the spinal reflex irritability, i. e., removal of some or all of the nervous centers above the medulla, also facilitate the convulsions. With regard to the localization of the mechanism of Brown-Séquard's "epilepsy" in the nervous system, it has been found: (a) that convulsions are present after removal of all the centers above the pons; (b) that they may be obtained from the pons, medulla and cervical portion of the cord when these structures are isolated; and (c) that they may also be obtained from the dorsal and lumbar portions of the cord after high dorsal section. As far as can be determined, the tracts of the cord that are involved are those of voluntary motion. The scratching reaction during anesthesia is regarded as the result of stimulation by the anesthetic of the same nervous mechanism as is involved in the "complete attack." The presence of "epilepsy" in the offspring of "epileptic" animals, Alford says, may be explained in other ways than by assuming inheritance, but Brown-Séquard's "epilepsy" cannot as yet be related to epilepsy in man.

92. **Heat Prostration Treated in Boston City Hospital.**—The treatment employed in these cases varied according to the kind of case. Exhaustion Type.—Dry rub, blankets, sometimes heaters, ice bag to the head and stimulation according to the individual case. Whiskey, aromatic spirits of ammonia, caffein and strychnin and occasionally epinephrin were used. Prostration Type.—Ice cap, ice pack, cold pack or sponge bath, according to the temperature, and rest in bed with moderate stimulation as above if there were signs of weakness. Heat-Stroke Type.—Here there are four indications: (1) Reduction of temperature, (2) maintenance of cardiac action, (3) control of convulsions, (4) treatment of complications. (1) Tub baths and ice packs were the choice in combating the high temperature. If the heart action was poor, the ice pack was always used as the patient need not be moved so much. Ice water enemata were used in a few instances, but as a rule a proper use of external measures seemed sufficient. (2) Maintenance of cardiac action often required stimulation of a heroic type, mostly hypodermically, as the patients were generally unconscious. Generous use of atropin was practiced for pulmonary edema, and strychnin, camphor and various forms of shock enemata were directed at the failing heart. (3) Convulsions were so frequent in the heat-stroke cases that it became the practice towards the end of the so-called epidemic to administer morphin and sometimes hyoscin with the plan of repeating the morphin in case convulsions nevertheless developed. (4) The treatment of complications as they occurred varied in no way from cases in which they were the primary disease. About five of these unconscious men required catheterization for retention of urine.

4. **Congenital Diaphragmatic Hernia.**—Rawes' patient was a baby which lived only twenty hours after birth. The following conditions were found at the necropsy: The right lung was small, measuring about 3 inches by 1 inch, the greater part of that side of the chest being empty. The left lung was extremely small and resembled a large raisin, the whole organ being about the size of a half-penny; filling the remainder of the left side of the chest was the stomach and the whole of the small and large intestine, with the exception of the descending colon and rectum. The small intestine was empty and massed together; the large bowel contained meconium, which could be expressed per anum. The greater curvature of the stomach was directed upward with the posterior surface of the organ lying anteriorly, so that the whole viscus was "upside down." The appendix was normal and measured 1½ inches. The heart was small and pushed over to the right side, although lying in close apposition to the left lung. The liver was normal in size and position. The pancreas and left kidney were bound down together in the left renal region. Both kidneys resembled a small walnut in size and presented a rough fissured surface. There was a large opening in the center of the left side of the diaphragm (with a smooth rounded edge), which would admit three fingers quite easily.

23. **Intracranial Murmurs and Tinnitus Aurium.**—Some facts and theories pertaining to intracranial physics and pathology which may, in part, serve to explain the origin of some of the entacoustical phenomena which may be appreciable not only subjectively by the patient as tinnitus, but also objectively by the observer as intracranial murmurs, are presented by Hyslop. He says that in cases in which the sheath of the auditory nerve is affected by an increase of pressure in the lymphatic fluid, direct stimulation of the nerve may cause subjective phenomena somewhat similar to those occurring in connection with the visual sense when the specific energy of the visual apparatus or tracts is irritated and manifested by symptoms ranging from scintillating scotomata to mere sparks of light or pressure phosphenes. Hyslop believes that such direct stimulation is rare except in cases in which degeneration of the auditory nerve is taking place. Another point to be noted is that, although pulsatile tinnitus is common, rarely do we have evidence of similar pulsatile phenomena in connection with any other of the cranial nerves which, in all probability, would be subject to somewhat identical conditions of influence. The point to recognize is that the fluid from the subarachnoid lymph spaces, when forced from the brain by increased intracranial blood-pressure, not only passes into the perilymphatic space of the labyrinth and thereby tends to modify the pressure of the endolymph, but it also serves as a more direct conducting medium for sound vibrations arising in connection with the pulsatile or other movements of the brain.

There are three different kinds of brain movements: (1) *Pulsatile movements communicated from the pulsations of* the large basal cerebral vessels; (2) respiratory movements, *in which the brain rises during expiration and falls during* inspiration; and (3) vascular elevations and depressions which alternate and are due to periodic dilatation and contraction of the blood-vessels. This last is a peristaltic arterial movement, regulated by the vasomotor center, and occurs from two to six times per minute. It is in connection with one or other of these movements that sound vibrations are apt to occur in the arterial, venous or lymphatic systems. The pulsatory movements of the brain are exceedingly interesting, and undoubtedly they most frequently give rise to intracranial murmurs. From the circle of Willis the arteries ascend and their currents are directed upward in the same direction as the venous currents. The large arteries at the base of the brain communicate a movement to it, each pulse wave raising it up and thereby compressing the cerebral veins. In expiration the venous blood is dammed back into the sinuses and the brain expands at the expense of the cerebrospinal fluid. During inspiration the veins are emptied by suction action, the brain collapses and the cerbrospinal fluid re-enters the cranial cavity. During these movements the cerebrospinal fluid is subjected to doubly compensatory movement, i. e., the pulsatile movement is mainly intracerebral and is concerned mainly with the passage of the fluid through the cerebral tissues and the ventricles, and the respiratory movement which is concerned mainly with the flow of the fluid to and from the cranium. Thus, it is that the vascular mechanism of the brain determines not only the intracerebral, arterial and venous movements, but it also serves to give a peristaltic movement to the ventricles of the brain, whereby the cerebrospinal fluid is slowly passed onward. Excess of cerebrospinal fluid within the cranium is not, as a rule, attended by tinnitus.

Anemia and hyperemia are powerful agents in modifying pressure equilibrium. The high arterial pressure which occurs in Bright's disease is attended by undue pressure on the peri- and endolymph, and gives rise to tinnitus. In hemicrania due to gout the intracranial arteries may be dilated or hyperextended, and by their more forcible action not only drive the cerebrospinal fluid from the cranial cavity, causing increased tension in the labyrinth, but, by the same process, force the brain toward the internal table of the skull and thereby render it possible for the pulsatile waves to come into almost direct contact with it. So it is in conditions of plethora culminating in apoplexy, of which tinnitus is an early symptom. Tinnitus is often a prominent and distressing symptom in anemia and chlorosis. From certain anatomic and clinical data there appears to be no doubt that intracranial venous murmurs may occur in the same way.

24. **Intestinal Hemorrhage in Typhoid.**—Whitehead cites cases to prove that intestinal hemorrhage gives rise to an increased formation of agglutinins in the blood lasting for a short time, which may help to tide the patient safely over a dangerous period. As a result of his investigations, Whitehead

recommends that, in many toxic cases of typhoid, and more especially in those in which the blood gives a poor agglutination reaction, phlebotomy to the extent of about 10 ounces (according to the physical condition of the patient) be tried as a treatment.

26. **Ophthalmo-Reaction of Calmette in Early Diagnosis of Phthisis.**—Hosford has never obtained a positive result, except in true cases, nor did he see any bad results whatever from the use of the test as regards the eye. If a patient in a suspicious case fails to give a reaction, then, he says, the test should be applied on three different occasions, with an interval between each application of from three to four weeks.

27. **Researches in Epilepsy.**—Attempts to produce an epileptic animal and researches on the blood and urine by Alexander gave uniformly negative results with one exception. There appears to be a relationship between the fit and a low urea-ammonia ratio.

30. **Flatulence.**—Ascertain the predisposing cause, says Burnet. and put the patient, if possible, on such a plan that he will gradually be able to eat all wholesome, though probably for a time, at least, very simple and light, articles of diet without discomfort and with great benefit to his general health and well-being. The less he comes to think of his diet and the more he is able, as time goes on, to forget his former flatulence and distention, the happier and better he will be. At first, no doubt in most cases the diet will have to be carefully chosen and somewhat restricted. A rather dry diet will be found to suit best in nearly all cases, little liquid being allowed with meals. This excludes all soups and broths at the beginning of a meal and allows of only a small quantity of fluid toward the close of the meal. What the special drink should be has to be decided in each particular case. Some will be best with plain water, others may require a little stimulant, alcohol in some form. Tea must be limited in quantity and must be freshly made. As a source of flatulence the excessive use of tea among well-to-do people should always be borne in mind. Animal food is, as a rule, best digested by these patients; it must be carefully selected and well, though plainly cooked—underdone rather than overdone. Much green vegetable will usually not be well borne, and what is given should be rubbed through a sieve, cooked as spinach is served. Often it is best to forbid potato, for a time, and to substitute toast or second day's bread. Farinaceous foods have to be given carefully and the effect watched, but where digestion by the stomach is chiefly at fault, starchy foods, as they are dealt with chiefly in the intestines, may be given in greater amount.

Nux vomica is one of the most useful remedies in these cases and it may be given in tincture, or in pill, with 1/4 grain of capsicum and 2 grains of compound rhubarb pill. Bismuth is of use in many instances, with an alkali such as bicarbonate of sodium and calumba or other bitter infusion. Salicylate of sodium with liquor pepticus, nux vomica and spirits of chloroform seems useful in a certain number of cases. Extract of malt given with or just after meals helps in those cases in which the digestion of starchy foods is obviously difficult. A few drops of dilute hydrochloric acid in water shortly after meals is often decidedly beneficial. In some cases iron and quinin seem to be indicated. A pill which is often well borne consists of 1 grain of reduced iron. with extract of nux vomica, quinin and pillula rhei compositus. It acts as a tonic and also as a mild aperient. It may be varied by 1 grain of pepsin and 1/20 grain of arsenious acid in place of the quinin and it is useful in anemic subjects. Calomel in very small fractional doses, given twice daily for a few days at a time, has often very good effect, and where there is sluggish action of the liver, 1 or 2 grains of blue pill with colocynth and hyoscyamin, or pillula rhei compositus should be given occasionally and followed, if necessary, by a mild saline in the morning, but anything like strong purgation should be avoided. When the distention is chiefly in the bowels, salicylate of bismuth, betanaphthol and salol, in cachet, give at least temporary relief. Lavage is not usually needed in these cases, but if there is much accumulation of mucus it is very helpful by clearing the stomach and thus giving a fair start to other treatment. In acute attacks of flatulence, hot water, with aromatic spirits of ammonia and spirits of chloroform with perhaps a teaspoonful of brandy, often relieves the tension and spasm. Sometimes a drop or two of oil of cajeput in mucilage has a very good effect.

32. **Measles.**—Good nursing is considered as of the greatest importance by Broadbent. Drugs are seldom required, he says, except for complications, which must be treated as they arise. For healthy children properly cared for in good homes an attack of measles for the most part runs a normal course and does not give rise to serious anxiety or call for special treatment. It is the neglect of precautions in the prodromal stages, the ignorance of the parents, the absence of proper care and treatment and the insanitary nature and surroundings so frequently met with in the homes of the poor which are mainly responsible for the high mortality.

37. **Backache.**—In searching for the cause of backache Berkeley says one must consider the vertebral column, the vertebral joints, the sacro-iliac joint, the coccyx, the spinal cord, the spinal membranes, the muscles of the back, the abdominal viscera, the aorta and the pelvic viscera. In addition, backache is found to be associated with the acute specific fevers and with neurosis.

39. **Biliousness.**—In no diseases, says Fenwick, is the employment of calomel and other mercurial preparations more abused, and it is highly probable that the daily recourse to calomel, which is such a common practice, produces extreme irritation of the duodenal mucous membrane. On the other hand, a dose of calomel or mercurial pill once a week followed by a saline the next day, always affords temporary relief to the nausea and giddiness. During an attack of febrile jaundice, due to acute cholangitis, the patient must remain in bed on a bland liquid diet. Tonics of all kinds are veritable poisons and only alkaline mixtures should be prescribed to relieve the symptoms of the secondary gastric and intestinal indigestion. The question of surgical interference should always be considered when clinical evidence points to the existence of gall-stones, chronic pancreatitis or duodenal ulcer.

43. **Morbid Blushing.**—The essential cause of morbid blushing in Campbell's opinion is an inherited morbid temperament. Drugs have little effect on it. The bromids are, on the whole, the most useful. Mild galvanic currents applied to the cervical sympathetic may do some good, but probably rather by suggestion than by their direct effect. The vasomotor centers of the face are readily affected by digestion: witness the liability to redden in the fact ofter taking food. Hence, a further need for paying attention to the digestive system in the subjects of morbid blushing. These patients may gain some confidence by using strong convex glasses. The artificial myopia thus induced by blurring the surroundings tends to diminish self-consciousness. Psychic methods are of undoubted value. Correct the patient's morbid outlook on life and to achieve this end it is necessary to get into close mental touch with him. Above all give him confidence.

September 1, XXIX, No. 17, pp. 1537-1632

53 *Syphilis of the Bladder and Upper Urinary Passages. (Syphilis de la vessie et des voies urinaires supérieures.) N. A. Mikhailoff.
54 Primary Tuberculosis of the Bladder. (De la cystite tuberculeuse primitive.) G. Li Virghe.

53. **Syphilis of the Bladder.**—Mikhailoff's patient was a woman of 39, the wife of a physician, who applied for relief from a sensation of weight in the kidney region and periodical hematuria which had been observed for five years. The kidney and other organs were apparently normal and she had borne a healthy child thirteen years before. The cystoscope revealed hyperemia in parts of the bladder, and around both ureter mouths there were small papules like those of impetigo; groups of the papules resembled roseola on the skin. The Wassermann test was applied twice, the first time with negative and then with positive results; under a course of mercurial pills and potassium iodid conditions were rapidly restored to normal.

Annales de Médecine et Chirurgie Infantiles, Paris

September 15, XV, No. 18, pp. 561-592

55 *Tuberculosis of the Testicles in Children. (Tuberculose testiculaire chez l'enfant.) P. Vignard and L. Thévenot.

57 Three Cases of Tuberculous Rheumatism. S. Veras.
58 Favorable Influence of Mountain Climate on Eczema in Infants. (Influence favorable de la cure d'altitude sur l'eczéma des nourrissons.) A. B. Marfan.

55. **Tuberculosis of the Testicles in Children.**—In one of the three cases reported, an infant of 14 months died six months after the first symptoms of tuberculous disease of the left testicle. Another child of 11 months died a week after removal of the tuberculous testicle. The tuberculosis in this case was primary. The third child was over 12 years old and the testicle had been giving trouble for a month and a half before the epididymectomy which put an end clinically to the local trouble. A review of the literature confirms this same predominance of infants among such patients. Of Jullien's seventeen, all but twelve were under the age of 2. The onset may be sudden and acute, the symptoms suggesting acute gonorrheal orchitis, but these subside in a few days leaving suppuration which soon forces its way outward. In other cases the onset is slow and indolent and the trouble is unsuspected until revealed by chance or an abscess ruptures.

60 Solitary Cysts in the Bones and Fibrous Ostitis. (Kystes solitaires des os et ostéite fibreuse.) P. Mauclaire and Burnier.

59. **Neurotomy for Endarteritis.**—Marquis reports two cases in which he successfully severed the nerves and put an end to the intense pain accompanying gangrene. In the first case the lesion was in the leg and the neurotomy is, he says, the sixth of the kind on record on the leg, while his other case is the first on record in which the operation was done for gangrene on the hand. He has been able to find in the literature only nineteen cases of gangrene on the hand for which neither syphilis nor diabetes was responsible. Conditions in the arm are so complicated by the anastomoses between nerves that a very complex operation would be necessary to ensure a complete cure. In his case the gangrene continued to spread, thus involving new nerves, with recurrence of pain after two weeks of freedom from it, and the patient died before the month was out. Marquis outlines the technic necessary in such cases to prevent recurrence of the pain.

Archives des Maladies de l'App. Digestif, Paris

August, V, No. 8, pp. 409-468

61 *Swallowing of Air in Connection with Acute Dilatation of the Stomach. (La distention aigue de l'estomac avec occlusion duodénale. Le rôle de l'aérophagie dans sa pathogénie.) A. Mathieu.
62 Absorption by the Large Intestine. (Sur l'absorption par le gros intestin.) G. Dienn.
63 Polycythemia with Predominating Dyspeptic Symptoms. (Cas de polycythémie rouge—maladie de Vaquez—avec symptomes dyspeptiques prédominants.) Wasserthal.

61. **Acute Dilatation of the Stomach with Duodenal Occlusion.**—Mathieu remarks that the discovery of the causes and remedy for this condition, which used to prove fatal in 75 per cent. of those affected, is one of the greatest triumphs of modern medicine. The main feature of the trouble is the immense distention of the stomach and upper part of the duodenum with its attendant symptoms and complications. The dilated portion stops abruptly where the mesenteric artery crosses and compresses the duodenum, and Mathieu shows in diagrams how any excessive distention of the stomach pulls down on the mesentery below the duodenum, thus tightening the pressure on the duodenum and starting the dangerous vicious circle. But, Mathieu queries, what starts the acute dilatation of the stomach, especially after operations? The syndrome has been observed in three cases of eclampsia and in cases in which exclusively medical measures had been applied, without any anesthetic. Consequently there must be some other causal factor in the syndrome besides the anesthetic, to which it is being universally ascribed. This factor, he asserts, is the swallowing of air; Lardennois has reported eight cases in which this fact was established beyond question. In one case he noticed that the patient after appendectomy, being tormented by thirst and dryness of the throat was constantly swallowing saliva and the air swallowed with it was progressively distending the stomach and causing great uneasiness. The condition was evidently the first phase of the dire "arteriomesenteric occlusion of the duodenum." When he explained to the patient the danger to which she was exposing herself, she ceased this insistent swallowing and conditions soon righted themselves, as also in his seven other cases of the kind. Mathieu was called once in consultation in a similar case of commencing dilatation of the stomach, and he introduced a cork between the patient's teeth whenever she began to retch, regurgitate or hiccough, thus preventing swallowing of air by keeping the mouth open. Improvement of the threatening symptoms was soon evident and by the second day all trouble from this source was at an end. The patient said afterward that the gag, the lavage of the stomach and the saline infusion had all helped in the cure, but above all the removal of the basin which had seemed to invite her to retch and try to vomit. The aerophagia, Mathieu affirms, is thus the primal factor in all these surgical and medical cases—the trouble having been observed even during convalescence from typhoid fever. There is no doubt a predisposition on the part of the stomach, some toxic or other cause weakening the stomach walls so that they yield more readily to the strain from the air swallowed in excess by the restless, nervous patients. The pressure from within may even close the cardiac orifice so that it may be impossible to introduce the stomach sound. Only in such an event need operative measures be considered, and they should be restricted to a minute gastrostomy to permit escape of the gases. In the eight cases on record in which a laparotomy was done and the stomach incised, the patients all died.

Archives de Médecine des Enfants, Paris

September, XIV, No. 9, pp. 641-720

64 *Functioning of the Kidney in the Course of Nephritis in Children. (Les fonctions rénales au cours des néphrites de l'enfance.) P. Nobécourt and P. Merklen.
65 Day Nurseries in Russia. (Les crèches en Russie.) W. Chenguelidze.
66 Diphtheria Bacillus-Carriers. (Diphtérie et porteurs de germes.) J. Michel.

64. **Nephritis in Children.**—Nobécourt and Merklen report research on acute nephritis in children, especially the simple albuminuric form, of which they report three typical examples, three of the form with retention of chlorids, and one with retention of nitrogen, as also a case combining these forms. They also analyze ten other cases of these various

types in a chronic form. Study of the elimination of albumin, chlorids and nitrogen allows the course of the kidney affection to be traced and explains the transient character of many cases of acute nephritis with great tendency to edema, and it also explains the tolerance of the children to certain forms of chronic nephritis. There may be phases of retention of chlorids in chronic nephritis, each simulating an acute disease. This intermittence is one of the features of nephritis in children. Nobécourt and Merklen expatiate on the advantages of a milk diet even when there is no retention of salt and urea; they found that the albuminuria was milder and briefer during scarlet fever when the children were restricted to milk for a time. If the albuminuric nephritis enters a chronic phase, a milk-vegetable diet is necessary, with yolks of eggs and very little meat, moderately salted. With retention of salt in acute nephritis, the children should be restricted to water and little of that for the first few days. The edema is generally rapidly reabsorbed when this is done. Even milk contains enough salt to prolong and intensify the edema during this phase. Salt should not be allowed until certain that the kidneys are able to eliminate it again. These dietetic measures may be supplemented by diuretics, such as lactose and theobromin or digitalis if the heart action is weak. In nephritis with retention of urea, they restrict the children to lactosed water, and avoid all albuminous substances until the permeability of the kidney for urea is restored. While milk is the main reliance in acute nephritis, it is not nourishing enough in the subacute and chronic cases, and it should be supplemented by unsalted food or food poor in nitrogen, according as the tests of kidney functioning point the way.

69 *Exclusion of the Duodenum and of the Pylorus. R. Leriche and E. Bressot.

68. Stenosis of the Pylorus of Tuberculous Origin.—Necropsy of a patient succumbing to chronic pulmonary tuberculosis revealed muscular thickening of the pylorus without any specific tuberculous changes, yet inoculation of guinea-pigs with scraps of tissue from this neoproduction resulted in the death of the animals from tuberculosis. This is the first case of inflammatory specific tuberculosis of the pylorus with positive inoculation of guinea-pigs. In adults fibrous or sclerous stenosis of the pylorus has only rarely been examined for tuberculosis; if this were done oftener, lesions suggesting inflammatory tuberculosis would certainly be found in many instances. The structure of the thickening in this case resembled so much that of myoma of smooth muscle tissue that it suggests the possibility that inflammation (tuberculous in this case) may be at the basis of true tumors (a benign leiomyoma in this case). The structure of the stenosis in this case resembled so closely the lesions encountered in the stenosis of the pylorus from muscular hypertrophy in the new-born, that it suggests a possible similar origin in the latter cases.

69. Exclusion of the Duodenum.—Leriche and Bressot describe the history of the operations excluding the pylorus and duodenum and the preferable technic, and then review fifty-nine cases, including two from their own experience; they also know of fifteen other cases without details. By exclusion of the duodenum they mean cutting the pylorus across and closing each stump with a suture, reestablishing the continuity of the digestive tract by a gastro-enterostomy. For exclusion of the pylorus, the operation has to be done on the stomach tissue proper and is thus more difficult than the simple severing of the duodenum at the pylorus, as the raw surfaces are more extensive. All the patients derived great benefit from the operation and no death is recorded. Jonnesco has performed the operation twenty-nine times without a fatality. The outcome is so good after exclusion of the duodenum that they insist that this should be the routine treatment for gastric or duodenal ulcer. They denounce this operation in cases of gastric cancer—this requires more radical measures but with gastric ulcer exclusion of the duodenum should be given the preference over pylorectomy (on account of the difficulty of the technic) and over gastro-enterostomy (on account of the inadequacy of the effect from this alone). The details of forty-five cases are given in full.

79 *Connection Between Hysteria, Renal Insufficiency and Retention of Salt. (Hystérie, insuffisance rénale, retention chlorurée.) J. Lépine.

76. Grippal Neurasthenia.—Bernheim reports twenty-three cases to illustrate the various forms of neurasthenia which influenza is liable to induce, in addition to its action on various organs. He is inclined to regard ordinary neurasthenia as an auto-intoxication, often constitutional, continuous or periodically recurring, and influenza may be the means of arousing this tendency to develop into actual neurasthenia. The symptoms of neurasthenia are refractory to suggestion, and they may persist for weeks or months or pass into a chronic stage with remissions and exacerbations, but the spinal and cerebral symptoms of neurasthenia only exceptionally merge into actual organic disease; persisting neuritis, tabes, myelitis or dementia are extremely rare as a consequence of neurasthenia or influenza.

79. Hysteria and Kidney Insufficiency.—Lépine's patient was an intelligent man of 51 suffering from traumatic hysteria which finally subsided. Study of this case and of the experiences of others seems to indicate that every hysteria has a toxic element, and that this can be sought on the part of the kidneys. This view explains the aggravation of conditions liable when there is retention of salt. This patient's serum contained twice the normal proportion of salt, and he finally succumbed to uremia.

81. **Anemia in Infants.**—Finkelstein remarks that the blood will often be found normal when the pallor of the infants suggests anemia. On the other hand, some infants are born with less than the normal reserve of iron to carry them along through the nursing period, as milk contains very little iron. This chlorotic type of anemia in nurslings has been described mostly by French writers. In Germany infants are given mixed foods earlier, and in consequence they get iron in time to prevent development of the anemia. The prematurely born and twins, and infants of frail, anemic and neuropathic mothers, do not have this normal reserve of iron. In such cases the lack of iron usually can be compensated by giving the child iron or mixed food, but in a certain proportion of cases there seems to be a constitutional weakness of the blood-producing apparatus. In a case of this kind in a male infant, both the mother and grandmother had a constitutional tendency to anemia. Hygienic-dietetic measures are the reliance in treatment, adding a little meat juice, cheese or half an egg, or fruit juice, vegetable soup, etc., to the milk. This generally answers the purpose, but if not a little saccharated ferrous carbonate, twice a day, generally is sufficient in the primary forms. With secondary anemia, removal of the cause is the first task, and blood tonics do more harm than good until this is done. His experience with pseudoleukemic anemia in infants seems to demonstrate that it is the extreme type of secondary anemia from toxic or infectious causes in children with a congenital debility of the blood-producing organs. If it is possible to keep the infant in pure air and free from complications with proper care and diet, the prospect of a cure of the pseudoleukemic anemia is good. Only in the uncomplicated cases and those in which iron has been given, does the anemia seem to respond favorably to arsenic.

82. **Arteriovenous Anastomosis for Gangrene.**—Glasstein reports a case of angiosclerotic gangrene of the left leg requiring amputation. Two years later the right leg became extremely painful. Persistence of the pains for eight months with chilliness of this leg, the livid tint and extreme tenderness, suggested impending gangrene, and when two cyanotic patches developed at the base of the great toe and no pulse could be detected in the popliteal, posterior tibial and dorsalis pedis arteries, the patient, a man of 38, consented to arteriovenous anastomosis at the root of the thigh. The Carrel technic was applied and in less than a month all pains had subsided and the foot was nearly of normal tint. When the patient was last seen, five months after the operation, complete function was restored and the leg had a normal aspect. He had been accustomed to smoke fifty or sixty cigarettes a day and was somewhat addicted to alcohol.

84. **Colloidal Nitrogen in the Urine in Cancer.**—Caforio investigated the urine of twenty-eight cancer patients and of twenty-two others to test the constancy of the increase in colloidal nitrogen which Salkowski thinks is specific for cancer. Caforio found the sign positive in pulmonary tuberculosis and liver disease as well as in cancer so that it is not pathognomonic for cancer, but negative findings are useful to exclude malignant disease. He never found the range above normal in the healthy or those free from organic disturbances, while it ran up to 7 per cent. with cancer even in the incipient stage, and subsided to normal range after the cancer had been excised.

86 *Tuberculin by the Mouth. (Stomachale Anwendung von [illegible] and W. Heinemann.
87 * [illegible] System by Muscular [illegible] d seine Erschöpfung [illegible] Carl.
88 * [illegible] Tölken.
89 [illegible] se.
90 *Inflamm [illegible] Ueber entzünd- liche [illegible]

86. **Inefficacy of Tuberculin by the Mouth.**—Möllers and Heinemann report extensive experimental research confirming the uncertain action of tuberculin administered internally, as the pepsin and trypsin in the digestive tract have a destructive influence on the specific elements of the tuberculin. The method is thus totally unfit for diagnostic purposes and even for treatment on account of the unreliability of the dosage, as it is impossible to calculate the amount that will eventually be absorbed.

87. **Exhaustion of "Chromaffine System" by Muscular Exertion.**—Carl says that the substance taking the chrome stain in the medulla of the adrenals, the paraganglia and the carotid gland—the apparatus called the "chromaffine system"—disappears in the frog under the muscular exhaustion from protracted reflex convulsions in strychnin poisoning.

88. **Appendicitis and Colitis.**—Tölken has been examining for evidence of colitis in all cases of appendicitis in his charge, and has found colitis more common than he expected. Circumscribed colitis and catarrhal conditions elsewhere in the large intestine are liable to prevail alone or as complications of appendicitis. The physiologic stagnation of the feces in the cecum naturally predisposes to inflammation in this region. Palpation shows a more extensive resistance than with appendicitis alone, and the tenderness is not so limited or so extreme as in the latter affection while the temperature, pulse and leukocyte count are nearer to normal range. In cases colitis is diagnosed, castor oil may show that operative treatment is not required.

90. **Inflammatory Tumors in Abdominal Wall.**—Heymann refers to a tumefaction years after a herniotomy which healed by primary intention. The slow development of the lesion suggests a malignant tumor, but examination always reveals some scrap of suture material as the primal cause. In a case reported in detail the tumor was evidently connected with the urachus and excision confirmed this assumption and the slight virulence of the germs causing the tumor-like infiltration. He advocates extensive excision.

91. **Heat Stroke as Factor in Summer Infantile Mortality.**—Rietschel argues that hitherto attention has been devoted too exclusively to the infant's food while the infant itself has been disregarded in our study of infantile mortality. He has found the mortality highest in the cities and in the hottest parts and in the hottest houses and rooms, and he has become convinced that the heat is an extremely important factor. It debilitates the children so that they feel any slight digestive disturbance far more severely and succumb more readily. The campaign against infant mortality is thus seen to be essentially a housing problem. He says that until the population began to accumulate in the cities, an excessive summer mortality among infants was known in Germany only from the reports in American literature, so that cholera infantum was long called the "American disease." Not until about 1870 did it attract attention in Germany, coincident with the industrial development and the migration to the cities. Among the arguments he presents for this view are that sterilizing the milk has not materially reduced infantile mortality, while the mortality fluctuates with the temperature, and especially with the temperature in the room where the child lives—this effect of heat may be evident even in winter, in overheated rooms. He adds that no one has been able to discover any actually toxic bacteria in milk, and if such were present they would proliferate just as well at 24 C. as at 30 C. He regards the morbidity as an actual heat stroke in many cases, or the heat may act as a chronic debilitating influence. Keep the milk cool, certainly, he says, but keep the baby cool first and foremost.

92. **The Thymus.**—Basch and Rohn use a special pleximeter with very narrow hammer for percussion with auscultation,

and state that it is thus possible to determine the outlines of the thymus even in infants, especially when combined with auscultation on friction of the region. In their examination of 140 children they found the normal outline of a rhomboidal shape, extending from the clavicle to the second or third rib, and bounded by the margin of the sternum and parasternal line. They give the area of dulness thus determined as compared with the necropsy findings in a number of cases. The area varies characteristically with the age and state of nourishment and with pathologic conditions in the vicinity.

94. **Technic for Local Anesthesia of the Trigeminus.**—Braun gives illustrated descriptions of ten different operations in the area innervated by the fifth cranial nerve for cancer or other serious lesion, all done under local anesthesia, blocking the main nerve-trunks. He declares that the advantages of local anesthesia are more evident in this than in any other field of surgery. The technic is somewhat similar to that of Schlosser's deep injections of alcohol for relief of trigeminal neuralgia, but it includes further the direct blocking of the nerve-trunks by injecting the anesthetic around it and infiltration of adjacent tissues, preceded by injection of morphin or morphin-scopolamin. One of the illustrations shows the total resection of the upper jaw and evacuation of the orbit for cancer in a man of 63, more than half of the face thus being opened up in a single yawning wound. There was very little bleeding, although the carotid was not ligated. The patient did not have to go to bed afterward and was strolling in the garden the next day. It is startling in one of the illustrations to meet the intelligent pain-free gaze of the patient, a man of 64, who was having a cancer of the base of the tongue, tonsil and fauces and the glands in the left side of the neck removed through the single large opening. Half of the tongue and jaw had just been cut out when the photograph was taken. Resection of the upper jaw, Braun adds, has lost its horrors under local anesthesia, and become an entirely different operation, as at any point elsewhere. With good local anesthesia and the patient quieted by morphin beforehand, the psychic influence of being a witness to the operation does not seem to disturb; its importance has been overestimated, Braun declares. The aim is to render the entire field free from pain without injecting directly into the diseased tissues.

105. **Vagotomy for Tabetic Gastric Crises.**—Exner severed the tenth, eleventh and twelfth dorsal roots to relieve tabetic gastric crises in a man of 47 and the pains were banished permanently, but the vomiting crises continued. This persistence of the vomiting feature of the crises, while the pains were abolished, convinced Exner that the primary trouble in the crises was some affection of the vagus or its centers, the vomiting thus indicating the primary feature of the gastric crises. Assuming this to be the case, treatment should be directed against the primary affection of the vagus or its centers, correction of which would be followed by the spontaneous arrest of the pains. The aim thus would be to sever the vagus on both sides just below the diaphragm, close to the cardia. In order to prevent any eventual spasm of the pylorus he reasoned that the pylorus ought to be kept open by a drain tube. On the basis of these theoretical assumptions he has performed this operation on two patients. In both the vagus was found much degenerated, quite enough to explain the gastric crises, he thinks. The first patient was relieved completely of the gastric crises, but still suffers from preexisting lancinating pains in legs and bladder. The second patient was very restless and pulled out the drain tube and the stomach became dilated, the atony increasing and the patient soon dying from inanition. A subphrenic abscess was found under the left lobe of the liver. Exner concludes from these experiences that it would be preferable to resect the vagus just below the diaphragm, before it ramifies. To avoid complications, a perforated drain should be passed through an opening in the stomach wall into the duodenum. It is probably safe to remove the drain by the end of the third week. He advocates this method of treatment, instead of rhizotomy, as liable to prove equally effectual, while it is far simpler and less dangerous than the Förster technic.

115 Dry Rot in Wood. (Ueber den Hausschwamm.) W. Wangerin.

108. **Tardy and Senile Osteomalacia.**—Curschmann asserts that non-puerperal osteomalacia is far more common than is generally assumed, and that frequently it is not recognized and the patients are treated on the wrong basis for assumed rheumatism, lumbago, sciatica, spondylitis or other spinal affection. The mistaken diagnosis is the more harmful, as treatment based on it is ineffectual, while phosphorus will cure the real trouble, the senile or tardy osteomalacia. During the last few years he has had twelve cases of pronounced osteomalacia in women approaching or just past the menopause. He advocates the term "tardy" osteomalacia for this form, as also for the tardy exacerbation of osteomalacia first developing during a pregnancy. One such case was in a woman of 43, whose osteomalacia developed during and subsided after her various pregnancies, and then recurred in a very severe form, seven years after the last pregnancy. He has encountered six cases of pronounced senile osteomalacia, and four of an abortive form, all but two of his osteomalacia patients being women. This rarity in men is one reason why it is so seldom recognized when it does occur in a man. In an instructive case of the kind a man of 65 had had severe osteomalacia for seven years, but no one had recognized it; the pains radiating to the sacrum and thigh had been diagnosed as sciatica. There were also pains in the chest in coughing, and the legs had grown stiffer and more painful until the man could only get around his room with support. Tentative antisyphilitic treatment gave no relief; neither did courses of treatment at Nauheim, Wiesbaden and elsewhere, to which he was sent by different

physicians in turn, with the diagnosis of gout, muscular rheumatism, chronic lumbago and finally sciatica, the history of treatments including a two-year course with a certain quack. But no measures gave permanent relief until Curschmann discovered the signs of severe osteomalacia, namely, extreme painfulness on pressure over the ribs, sternum or spine; moderate round dorsal kyphosis, the lower ribs resting on the bony framework of the pelvis; a transverse groove in the skin across the epigastrium and contracture of legs, especially of the adductors in standing and walking, the patient taking with great difficulty the shortest of steps, the thighs pressed close together, and stopping exhausted after a minute or two. On reclining the muscles relaxed. The tendon reflexes were normal. Under phosphorus, bed rest and baths the spontaneous pains disappeared entirely in four weeks, and in another month the patient was able to walk normally, without pain, and return to business. The lack of recognition of osteomalacia in this case had given the patient seven years of martyrdom. All these patients were well-to-do, and the osteomalacia developed very insidiously and slowly in all but one case in which it reached its acme in two months. The chest, spine and thighs are mainly affected in this senile and tardy form, the pelvis least or not at all. There was no tendency to paralysis in any of his cases, but in five of his six cases of senile osteomalacia, numbness and paresthesia in hands and feet suggested neuritis at first. The angiospastic symptoms subsided as the osteomalacia was cured. In two cases of the tardy form there were trophic disturbances in face, fingers or nails, but no trace of any complicating organic disease, mental disturbances or hysteria in any instance. The height was reduced a little, 5 cm. in one case. The efficacy of phosphorus in cod-liver oil in these cases confirms the diagnosis. He gives from five to three teaspoonfuls of a 0.01 per cent. solution at first, gradually dropping to one or two teaspoonfuls, but keeping this up for months; in two cases for nearly a year. The phosphorus has to be given continuously, like iodid in arteriosclerosis or thyroid in myxedema. The benefit from phosphorus-cod-liver oil confirms the assumption that rachitis and osteomalacia are essentially the same affection. Curschmann adds in conclusion that in the tardy and senile form of osteomalacia, castration without a preceding energetic and long-continued course of phosphorus treatment is actual malpractice.

112. **Salt-Poor Diet.**—Leva calls attention to a number of seasonings which can be used in place of salt in various dishes, such as mint thyme, capers, onions, laurel leaves, celery and cress, lemon, vinegar, mustard and sugar, disguising the lack of salt. Caper sauce, tomato sauce, madeira sauce, etc., mayonnaise and the copious use of cream, enable one to dispense with salt to an unanticipated extent. It is not a difficult matter to have the baker keep out enough unsalted dough to supply a function unsalted bread. It can be made more palatable by having this loaf shortened with unsalted butter; in some countries, especially Italy, a large part of the population always use unsalted bread. Leva has been experimenting with sodium bromid as a substitute for salt, saying that the use of 1 or 2 gm. a day for a time would do no harm in the majority of cases, while it seasons bread, eggs, soups and vegetables in a fairly satisfactory manner. It does not taste like salt, but it enables the salt to be dispensed with better. His experiments have demonstrated that sodium bromid promotes the elimination of sodium chlorid, and thus indirectly of dropsical fluid, and it can usefully supplement the dietetic measures.

114. **Negative Differential Pressure in Treatment of Heart, Lung and Vascular Disease.**—Pick has used Bruns' apparatus for negative differential pressure in a number of cases, and has found that it arrests asthma, and aids in the cure of emphysema of the lungs and bronchial catarrh, while it regulates the circulation by promoting the reflux of blood from the periphery to the left heart by the aspirating action of the negative pressure. Not only the heart but the entire vascular system benefits by this. The method is thus peculiarly useful, he says, in arteriosclerosis. Respiration under the negative pressure is like that at high altitudes; the result is an expanding of the chest and strengthening of the breathing apparatus, stimulating the blood-producing organs to better functioning.

128 Treatment of [illegible] in General, Especially in Abortion. [illegible] und ihre Behandlung.) H. Schottmüller. Commenced in No. 39.

120. **Warming the Anesthetic Fumes for Major Operations.**—Läwen states that complications on the part of the lungs follow in about 5 per cent. of all the laparotomies at the Leipsic clinic, even those done under local anesthesia. He is convinced that the essential factor is the impossibility of adequate expectoration after the operation; at the same time chilling probably contributes, and he has devised a contrivance to add to the apparatus for mixed oxygen and ether or chloroform inhalation anesthesia, which warms the fumes. In twenty-seven operations performed with this technic the results seemed to be excellent, and he thinks that possibly this method may prove useful in protracted laparotomies or operations leaving extensive raw surfaces, such as amputation of the breast, or when the patients are in shock or have lost an excessive amount of blood.

121. **The Early Stages of Deforming Spondylitis.**—Plate calls attention to the necessity for early diagnosis of this affection in order to prevent aggravation later. By treatment as for inflamed flat-foot, radiotherapy with arc-light baths, supplemented by strong irritation to the skin (by grandination), and with a supporting corset in the chronic forms, it is possible to cure or relieve to a great extent. The benefit derived confirms his assumption of the trouble as loss of the elasticity of the intervertebral disks; they are crushed down and the upper edges of the bodies of the vertebræ become jagged. These changes are readily seen with the Roentgen rays and it is thus possible to differentiate the condition when the patients complain of pains in the back when they walk, stand or sit, which vanish at once when they recline. No other spinal affection has this characteristic of the disappearance of the pain on lying down. In walking the patients try to avoid shaking the spine; they take short cautious steps, not stretching the knee, and striving to spare the spine by grasping the thigh with the hand. No tendency to curvature was noticed in any case, and although pressure and tapping the spine cause pain or aggravate existing pain, yet it is never so intense as with tuberculous or other severe spinal lesions. His patients were all men forced to bear heavy loads or push heavily laden small carts, and a number were under 50 years old. Roentoscopy is especially instructive when the spine is examined sagittally.

122. Nail Extension for Fractures.—Koerber has applied Steinmann's nail extension in seventy cases of fracture, and considers the method useful in cases in which there are obstacles to the Bardenheuer adhesive-plaster extension technic, or the ordinary methods of treatment prove inadequate, but says that it is not a standard method for the ordinary run of cases, and it is not ripe for introduction into general practice.

127. Operative Treatment of Tuberculous Lungs by Total Mobilization of Chest Wall: Thoracoplastic Pleuro-Pneumolysis.—Friedrich's work in this line is familiar to American readers (The Journal, 1909, LIII, 1970). He here reviews his experiences to date and emphasizes the fact that fourteen of his patients are in fairly good health to date who were saved by his operation during the last four years when the severe general symptoms accompanying the progressing tuberculous cavity in the lung foretold a speedy demise. The fine results obtained from immobilizing the lung by induced pneumothorax encouraged him to operate in this way in cases in which there were obstacles to the therapeutic pneumothorax. Quincke was the pioneer in this line in 1888, and the Marburg clinic has pressed forward in this path, having now a record of twenty-eight operations, resecting more or less of the ribs over the cavity. Experience has shown that recent metastasis in other organs, larynx, intestines or bones, contra-indicates the operation. Six of the total eight cases with a fatal outcome were of this class, which is now excluded from this method of treatment. Patients under 15 and older than 40 are likewise excluded, but persistent fever and swarms of bacilli do not necessarily contra-indicate the operation. Some of the most successful cases were of this class. The total mortality of twenty-six per cent. in these twenty-six cases of progressing tuberculous cavity-production certainly is far from disheartening. The main point is to be certain that the chest wall and the pleura have become hard and stiff under the influence of the irritation. If they give way under the pressure after the ribs are resected, and sink down on the sound lung, its functioning is impaired and the operations fail to benefit. Normal functioning of the other lung is indispensable to success, but it is not necessary always for it to be entirely sound. The operation is less serious, while the outcome seems equally good, when the ribs are resected through an incision in the axilla, a longitudinal incision through the serratus, folding in the lips of the soft parts like a cushion over the stumps of the ribs, pushing back the pleura and lung and suturing the skin to reduce the girth. He shows in some diagrams how this technic compresses the lung between the spine and the sternum. This technic has several advantages but it is harder to detach the first rib, and the brachial plexus may be injured while functioning of the serratus may be impaired more than with other technics. A number of typical cases are described in detail, with diagrams to illustrate the special conditions. In one case all three right lobes were infiltrated, with multiple cavities; the operation was aimed only at the two upper lobes, the third lobe being left until one year later when the patient, a physician of 25, had recuperated wonderfully. In a number of cases, recurring severe hemoptysis was the stimulus to operation, which proved thus a direct life-saving measure in some instances. The cavities shriveled up so quickly that no need was felt for direct local cauterization, but the possibility of this should not be forgotten with this thoracoplastic pleuropneumolysis.

147 *Blocking of the Brachial Plexus. (Die Anästhesierung des Plexus brachialis.) D. Kulenkampff.

147. Regional Anesthesia by Blocking the Brachial Plexus.—Kulenkampff has applied the technic of which he gives an illustrated description in twenty-five cases. The result was complete anesthesia of the entire arm in fifteen and anesthesia of enough of the arm for the desired operation in five others, while the other five cases were operated on during the tentative experiments with the technic. The best point of access to the plexus is just above where it is crossed by the omohyoid muscle and the transversalis colli artery. The patient seated, the subclavian artery is located by palpation or even by the eye, the head held in the proper position. The subclavian can generally be located at the point where if the external jugular vein were extended it would cut across the clavicle. The needle is inserted at this point, close to the upper margin of the clavicle, seeking to touch with the needle one of the arm nerves. On contact with the nerve there is tingling in the arm and motor phenomena but no pain. If the needle has been pointed correctly these paresthesias develop as soon as the skin and deep fascia have been pierced. The point of the needle must be directed toward the tip of the second or third thoracic spinous process. If the needle butts against the first rib without reaching the plexus, it has been introduced too far toward the side; the sign that the nerve has been reached is the appearance of the paresthesias. The anesthesia induced by the nerve-blocking injections lasts from ninety minutes to two or three hours. The only pain during the entire procedure and operation is from the prick to make the little infiltration blister through which the needle is introduced into the depths.

150 *Galvanic Electrotherapy in Amenorrhea. O. Rigamonti.

October 1, No. 118, pp. 1243-1258

151 Physiology of Secretion of Urine. I. (La secrezione dell'urina.) F. Bottazzi.
152 Diagnostic Importance of Variation in Temperature in the Axillæ. (Sul valore diagnostico delle differenze termometriche tra le due ascelle.) D. Miotto.

150. Electrotherapy in Amenorrhea.—Rigamonti applies one pole with the galvanic current to the sacrum and the other to the hypogastrium, and reports three cases of amenorrhea in which this treatment proved effectual although the trouble was of a different origin in each. In one, menstruation ha been arrested by a fright, in another the condition suggest possibly incipient tuberculosis, and in the third case there was chlorosis. The patients were from 19 to 28 years old, and the symptoms from the suspended menstruation were about the same in all. From thirty to forty sittings were given, daily at first and then at longer intervals.

156 *Successful Resection of Scapula for Enchondroma. (Resezione subtotale della scapola per voluminoso encondroma. Guarigione.) L. De Gaetano.

156. **Resection of the Scapula.**—Gaetano reports excellent functional outcome in a young man whose scapula was resected on account of a large enchondroma two years ago. The functioning of the arm is scarcely interfered with, the patient being able to lift a 200-pound weight. He knows of twenty-seven operations of the kind on record, which he tabulates, the outcome being constantly favorable since 1870, with exception of one case in which the patient succumbed to metastasis of the sarcoma.

157 *Gunshot Wounds of the Heart. (Om skottskador på hjärtat.) S. Sjövall.
158 *Coincident Similar Mental Disease in Twins. (Fall af psykos hos tvillingar.) E. Göransson.
159 *Whooping-Cough in Connection with Spasmophilia. (Om pertussis och pertussisliknande katarrer samt deras förhållande till den spasmofila diatesen.) W. Wernstedt.
160 **Torsion of the Spermatic Cord. (Om torsion of sädessträngar.)* O. Löfberg.

157. **Gunshot Wounds of the Heart.**—Sjövall devotes nearly ten pages to tabulation of the details in thirty-one operative cases of this kind, including one from his own experience. These data show that the patient stands a much better chance when a proper operation is done than under expectant treatment. In sixteen cases apparently complete restitution followed suture of the wound.

158. **Psychosis in Twins.**—Göransson reviews the fifty cases on record of a similar form of mental impairment in twins, and reports a case of the kind from his own experience. His patients were women 23 years old, and the psychosis came on suddenly in both with less than two months' interval. It was of the confusional type with agitation in one and stupor in the other, and with complete recovery in two or three months.

159. **Whooping-Cough and Spasmophilia.**—Wernstedt has been examining children with pertussis during a recent epidemic to determine the electric excitability. He found a constant connection between the severity of the spasmodic coughing and the reaction to the electric tests. His findings suggest a close connection between the spasmophilic diathesis and the pertussis, and he thinks that both the former and severe forms of the latter are an indication of a neuropathic constitution.

160. **Torsion of the Testicle.**—Löfberg reports three cases and refers to seventy-six on record. Two of his patients were infants less than a year old, the third a man of 28; the torsion was the result of trauma in this case. Castration had to be done in 76 per cent. of the cases on record.

161 *Chronic Appendicitis. (Undersøgelser over kronisk Appendicitis.) V. Scheel.
162 Vaccine Therapy of Alveolar Pyorrhea. (Pyorrhoea alveolaris og dens Behandlung med Injektioner af autogen Vakcine.) O. Drescher.

161. **Chronic Appendicitis.**—Scheel has examined the appendix after extirpation in 164 cases. He found signs of chronic inflammation in fifty-eight of the eighty-five cases in which the appendicitis was supposed to be merely an acute lesion, and he is inclined to think that in most of the so-called chronic appendicitis cases, the trouble was inflammation of the cecum as well. Inflammation of the cecum has many ups and downs, and there may be long intervals of latency. It is possible that the cure ascribed to the appendectomy in many instances may have been merely the effect of the rest in bed and dieting, or it may have been coincident with a spontaneous remission.

Books Received

Books received are acknowledged in this column and such acknowledgment must be regarded as a sufficient return for the courtesy of the sender. Selections will be made for review in the interests of our readers and as space permits.

Lehrbuch der Hyperämiebehandlung akuter chirurgischer Infektionen. Theorie und Praxis für Aerzte und Chirurgen. Von Dr med. Eugen Joseph, Privatdozent der Chirurgie an der Friedrich-Wilhelms-Universität Berlin. Mit einem Vorwort von Prof. August Bier. Paper. Price, 7 marks. Pp. 283, with illustrations. Leipzig: Dr. Werner Klinkhardt, 1911.

Dental Disease in Its Relation to General Medicine. By J. F. Colyer, L.R.C.P., M.R.C.S., L.D.S., Dental Surgeon to Charing Cross Hospital and the Royal Dental Hospital, England. With the Assistance of Stanley Colyer, M.D. (Lond), M.R.C.P., D.P.H. Cloth. Price, $1.60 net. Pp. 189, with 62 illustrations. New York: Longmans, Green & Co., 1911.

The Report of the Philadelphia Milk Show. Its Organization and Management and a Description of the Exhibits. Edited by Arthur Edwin Post, Executive Secretary. Paper. Dr. Joseph S. Neff, Chairman of the Executive Committee, 1912 Chestnut Street, Philadelphia. Pp. 123, with illustrations. Published by the Executive Committee, 1911.
